Ny dansk patentansøgning Symbicom Aktiebolag OspH antigens from Borrelia Vor ref: 19177 DK 1

> Patents Trademarks Designs Copyright Licensing Documentation European Patent Attorneys European Trademark Attorneys Copenhagen London Munich Boston Alicante

FIELD OF THE INVENTION

The present invention relates to nucleic acid sequences encoding antigenic lipoproteins associated with Borrelia burgdorferi sensu lato (Borrelia burgdorferi sensu stricto, Borrelia garinii, and Borrelia afzelii; collectively designated Bb hereinafter), particularly polypeptides associated with virulence; vaccine formulations comprising these polypeptides are also part of the invention. The invention also relates to methods for producing Bb immunogenic polypeptides and corresponding antibodies. Other embodiments of the invention relate to methods for detecting Lyme disease and transformed cells comprising Bb-associated nucleic acids.

BACKGROUND OF THE INVENTION

Lyme disease is a multi system disease resulting from tick
transmission of the infectious agent, Bb (Rahn and Malawista,
1991). Although recognised as a clinical entity within the
last few decades (Steere et al., 1977), case reports resembling Lyme disease date back to the early part of the 20th
century. Cases of the disease have been reported in Europe,
20 Asia and North America (Schmid, 1985). Despite a relatively
low total incidence compared to other infectious diseases,
Lyme disease represents a significant health problem because
of its potentially severe cardiovascular, neurologic and
arthritic complications, difficulty in diagnosis and treatment and high prevalence in some geographic regions.

Bb is not a homogeneous group but has a variable genetic content, which may in turn affect its virulence, pattern of pathogenesis and immunogenicity. Lyme borreliosis associated borreliae are so far taxonomically placed into three species, Borrelia burgdorferi sensu stricto, Borrelia garinii, and Borrelia afzelii (Burgdorfer et al. 1983, Baranton et al. 1992, Canica et al. 1993). It is well documented that considerable genetic, antigenic and immunogenic heterogeneity occurs among them, as well as among the strains within the

30

separate species (Baranton et al. 1992, Canica et al. 1993, Zingg et al. 1993, Wilske et al. 1993, Adam et al. 1991, Marconi and Garon 1992). The major evidence of this phenomenon is provided by the molecular studies of the plasmid-5 encoded outer surface protein A (OspA), OspB and OspC (Barbour et al. 1984, Jonsson et al. 1992, Wilske et al. 1993, Marconi et al. 1993). In different animal models efficient protection is achieved by passive and active immunisation with OspA (Schaible et al. 1990, Fikrig et al. 1992, Erdile 10 et al. 1993), therefore, OspA remains one of the main candidates for Borrelia vaccine. It is unclear, however, whether inter- and intra-species heterogeneity of OspA, as well as other competitors for immuno prophylaxis, allow efficient cross-protection (Fikriq et al. 1992, Norris et al., 1992). 15 Furthermore, it was recently suggested that certain protective antibodies produced early in the course of Borrelia infection is unrelated to OspA (Norton Hughes et al. 1993, Barthold and Bockenstedt, 1993).

Its virulence factors, pathogenetic mechanisms and means of immune evasion are unknown. At the level of patient care, diagnosis of the disease is complicated by its varied clinical presentation and the lack of practical, standardised diagnostic tests of high sensitivity and specificity. Antimicrobial therapy is not always effective, particularly in the later stages of the disease.

Variation among Bb strains and species and the changes resulting from in vitro passage add to the problems of developing vaccines or immuno diagnostics from either the whole organism or specifically associated proteins. Using a PCR assay, it was found that one set of oligonucleotide primers was specific for North American Bb isolates, another for most European isolates and a third set recognised all Bb strains (Rosa et al., 1989).

Serological assays for the diagnosis and detection of Lyme 35 disease are thought to offer the most promise for sensitive and specific diagnosis. However, serologic assays generally use whole Bb as antigen and suffer from a low "signal to noise" ratio, i.e., a low degree of reactivity in positive samples, particularly early in the disease, as compared to negative samples. This problem results in high numbers of false negatives and the potential for false positives. Background reactivity in negative controls may be due in part to conserved antigens such as the 41K flagellin and the 60K "Common Antigen". These Bb proteins possess a high degree of sequence homology with similar proteins found in other bacteria. Therefore normal individuals will often express anti-flagellar and anti-60K antibodies. Unique, highly reactive Bb antigens for serological assays are therefore desirable but heretofore unavailable.

Diagnosis of Lyme disease remains a complex and uncertain endeavour, due to lack of any single diagnostic tool that is both sensitive and specific. Clinical manifestations and history are the most common bases for diagnosis. However, there is a pressing need for specific, sensitive, reprodu-20 cible and readily available confirmatory tests. Direct detection offers proof of infection but is hampered by the extremely low levels of Bb that are typically present during infection, as well as the inaccessibility of sites that tend to be consistently positive (e.g., heart and bladder). Cul-25 ture, although sensitive, is cumbersome and requires 1-3 weeks to obtain a positive result. PCR appears to offer promise in terms of direct detection (Lebech et al., 1991) and indeed Goodman et al (1991) have reported detection of Bb DNA in the urine of patients with active Lyme disease using a PCR method. However, it is unlikely that PCR assays will 30 become commonly used in clinical laboratories because of the degree of skill required for its use and the high risk of DNA contamination.

Another problem in detection of Lyme disease is the substantial number of humans exposed to Bb who develop unapparent or asymptomatic infections. This number has been estimated as high as 50% (Steere et al., 1986).

There is clearly a need for means of preparing Bb-specific antigens, e.g., for the development of diagnostic tests for

5 Lyme disease. Adequate assays do not exist and should ideally meet several criteria, including (1) expression of an antigen by all pathogenic Bb strains, (2) elicitation of an immune response in all Lyme disease patients, (3) high immunogenicity with a detectable antibody response early in the infection stage, (4) antigens unique to Bb without cross reactivity to other antigens and, (5) distinction between individuals exposed to non-pathogenic as opposed to pathogenic forms of Bb.

There have been several studies describing low molecular

weight lipoproteins that have not been identified as outer surface proteins (Osps). Katona et al showed the presence of a major low-molecular weight lipoprotein specific for B.

burgdorferi and raised the possibility that it was a borrelial equivalent of Braun's lipoprotein (Katona et al., 1992).

Another study reported an immunogenic 14 kDa surface protein of B. burgdorferi recognised by sera from Lyme disease patients (Sambri et al., 1991). A 14 kDa mitogenic lipoprotein of B. burgdorferi was reported by Honavar et al. (1994).

25 Sadziene et al. (1994) when analysing an Osp-less B. burg-dorferi strain identified a 13-kDa surface exposed protein which was designated p13.

OBJECT OF THE INVENTION

It is an object of the invention to provide novel nucleic 30 acid fragments and polypeptide fragments which are useful in the preparation of diagnostics and prophylactic means and compositions relating to infections with Bb. It is a further object to provide novel vaccines and diagnostic means as well as methods for the preparation and use of such vaccines and diagnostic means. Finally, it is an object of the invention to provide tools such as vectors and transformed cells which facilitates the preparation of the polypeptide fragments and the vaccines.

SUMMARY OF THE INVENTION

The inventors have surprisingly found that an antigen from Bb with an apparent molecular weight of 13 kDa (determined by SDS-PAGE, and subsequent visualization such as staining with 10 Coomassie Blue) is highly conserved in the three strains B. burgdorferi sensu stricto B31, B. garinii IP90, and B. afzelii ACAI, whereas this antigen cannot be found in Borrelia species related to relapsing fever and avian borreliosis. The disclosed antigens therefore are excellent candidates for 15 vaccines and diagnostics relating to infections with Bb. The full-length antigens will be termed OspH (outer surface protein) herein, since it has been shown by the inventors that the protein natively is a lipidated outer surface protein and therefore should be categorized together with other Osps from Borrelia burgdorferi sensu lato.

The present invention thus addresses one or more of the foregoing or other problems associated with the preparation and use of Bb specific antigens, particularly those antigens which are associated with virulence and which are useful for developing detection and diagnostic methods for Lyme disease. The present invention involves the identification of such antigens, which herein is designated OspH (outer surface protein H) as well as the identification and isolation of Bb nucleic acid sequences that encode OspH antigens or antigenic polypeptides derived therefrom. These sequences are useful for preparing expression vectors for transforming host cells to produce recombinant antigenic polypeptides. It is further proposed that these antigens will be useful as vaccines or

25

immuno diagnostic agents for Bb associated diseases such as ...
Lyme disease in particular.

The DNA of the present invention was isolated from Bb. The microorganism is a spiral-shaped organism approximately 0.2 micron in diameter and ranging in length from about 10-30 microns. Like other spirochaetes, it possesses an inner membrane, a thin peptidoglycan layer, an outer membrane, and periplasmic flagella which lie between the inner and outer membranes. Bb is obligate parasite found only in association with infected animals and arthropod vectors in endemic areas. Bb-like organisms have also been identified in birds raising the possibility that birds could also serve as an animal reservoir. While some Bb isolates have been cloned, most isolates have not been cloned and most likely represent mixtures of different variants even at the time of culture origination.

Bb has similarities with other relapsing fever organisms such as B. hermsii. Bb has a single chromosome with two unusual features, linear conformation and small size (approximately 900 kilobase pairs). Fresh isolates of Bb contain up to four 20 linear plasmids and six circular supercoiled plasmids. The plasmid content of different Bb isolates is highly variable. For example, in one study only two of thirteen strains had similar plasmid profiles. Some plasmids are lost during in vitro passage which may correlate with loss of virulence. Outer surface proteins OspA and OspB are encoded on the 49 kbp linear plasmid. The OspH membrane-associated/outersurface proteins discovered by the inventors is encoded on the Bb chromosome. The OspH protein gene being localised to the chromosome of borreliae shows a higher degree of conservation 30 among Lyme disease associated borreliae contrary to the plasmid-encoded major outer surface proteins A, B, and C which exhibit a significant species and strain dependent genetic and antigenic polymorphism (Barbour 1986, Jonsson et al. 1992, Wilske et al. 1993). Furthermore, the level of similarity and identity between the deduced amino acid

sequence of the OspH protein from different borrelia strains further shows that this protein can be useful as a vaccine against Lyme disease as well as a target for diagnostic use.

In order to identify DNA segments encoding the OspH proteins, purified protein was isolated from B. burgdorferi B313, by preparative SDS-PAGE for subsequent use in amino acid sequencing. Attempts to N-terminally sequence the purified protein by standard techniques was unsuccessful. The protein was therefore subjected to V8 protease cleavage. After protease cleavage the peptide was transferred to polyvinylene diffusable membranes, sequence analysis was performed using standard sequencing techniques (Matsudaira, 1987). A 25 amino acid sequence was identified (SEQ ID NO: 1).

DNA libraries were prepared by restriction enzyme digestion of DNA prepared from the strains *B. burgdorferi* B31, *B. afzelii* ACAI and *B. garinii* Ip90.

Codons for the amino acid sequence obtained, SEQ ID NO: 1, were selected by reverse translation based on (1) conclusion that codons containing A or T were favoured and (2) knowledge of published DNA sequences for several Bb proteins. A choice favouring A or T containing codons was based on the observation that the G + C content of Bb is only 28-35% (Burman et al. 1990). Two oligonucleotides were synthesized having the sequences shown in SEQ ID NO: 2 and SEQ ID NO: 3. These were used as primers in a PCR reaction with DNA prepared from B. burgdorferi B31 as template. The amplified fragment was sequenced, SEQ ID NO: 4, and verified to code for the amino acid sequence, SEQ ID NO: 1.

A DNA probe, designated Y7 (SEQ ID NO: 7), was designed used as a to screen the DNA library prepared from B. burgdorferi B31 in a attempt to identify DNA encoding the OspH protein from this Bb species. This attempt proved unsuccessful.

An RsaI restriction site identified in the DNA sequence of the PCR fragment was used in a further attempt to clone the ospH gene. Bb DNA was digested with RsaI and the fragments cloned into a pUC plasmid. Further PCR amplification using the sequence identified surrounding the RsaI site yielded DNA fragments which were found to code for the OspH protein.

The identified sequence of the ospH gene from B. burgdorferi B31 was used to design PCR primers which were subsequent used to clone the ospH gene B. afzelii ACAI and B. garinii Ip90.

The deduced amino acid sequences of OspH from B. burgdorferi 10 B31, B. afzelii ACAI and B. garinii Ip90 were analyzed and it was found that the N-terminal region of the deduced amino acid sequences are typical of the signal peptides of bacterial lipoproteins. The N-terminal methionine is followed by a hydrophobic region and a signal peptidase II recognition 15 sequence. The signal sequences, Leu Ala Thr Phe Cys for B. burgdorferi B31, Leu Leu Ala Phe Cys for B. afzelii ACAI and Leu Val Ile Phe Cys for B. garinii Ip90, differed somewhat from the consensus signal peptidase II recognition sequence (Leu Xaa Xaa Cys) found in most bacteria, but resembled the cleavage sequence Leu Ser Ile Ser Cys of the outer surface protein D (OspD) of Bb and Leu Met Ile Gly Cys of the variable major proteins Vmp7 and Vmp21 of B. hermsii. These surface antigens have been shown to be lipoproteins (Norris et al. 1992; Burman et al. 1990). The presence of 25 this leader sequence implied the mature OspH proteins are translocated across the cytoplasmic membrane and are anchored to the cytoplasmic membrane and/or outer membranes via fatty acids associated with an N-terminal cysteinyl residue. Lipidated forms of the outer surface protein A (OspA) from Bb 30 have been shown to be more immunogenic that non-lipidated forms of OspA (Erdile et al. 1993).

Therefore, an important part of the present invention relates to lipidated OspH polypeptides, *i.e.* lipidated versions of the polypeptides of the invention.

35

Antigenicity of the OspH protein was verified by immunisation of a rabbit. Antiserum collected from rabbits injected with the OspH protein prepared from B. burgdorferi B313 was found to recognise the OspH protein of B. burgdorferi B31, B. afzelii ACAI, and B. garinii Ip90. There was no apparent reactivity of the antiserum with B. hermsii, B. crocidurae, B. anserina.

The OspH protein which has been cloned by the inventors of the present invention has been shown to have a molecular

10 weight of about 19,000 but nevertheless to be identical to a protein from Bb which has an apparent molecular weight in SDS-PAGE of 13 kDa. This surprising difference between true and apparent molecular weight has not been explained (although it is of course somehow related to the motility of OspH in an SDS gel). It should be understood though, that when the terms "13 kDa protein" or "13 kDa antigen" or "13 kDa polypeptide" are used in the present specification and claims, this is an alternative designation of the OspH polypeptide having an M_r of approx. 19,000.

The nucleic acid segments of the present invention encode antigenic amino acid sequences associated with Bb. These sequences are important for their ability to selectively hybridise with complementary stretches of Bb gene segments. Varying conditions of hybridisation may be desired, depending on the application envisioned and the selectivity of the probe toward the target sequence. Where a high degree of selectivity is desired, one may employ relatively stringent conditions to form the hybrids, such as relatively low salt and/or high temperature conditions. Under these conditions, little mismatch between the probe and template or target strand is tolerated. Less stringent conditions might be employed where, for example, one desires to prepare mutants or to detect mutants when significant divergence exists.

In clinical diagnostic embodiments, nucleic acid segments of the present invention may be used in combination with an

appropriate means, such as a label, to determine
hybridisation with DNA of a pathogenic organism. Typical
methods of detection might utilise, for example, radioactive
species, enzyme-active or other marker ligands such as
avidin/biotin, which are detectable directly or indirectly.
In preferred diagnostic embodiments, one will likely desire
to employ an enzyme tag such as alkaline phosphatase or
peroxidase rather than radioactive or other reagents that may
have undesirable environmental effects. Enzyme tags, for
example, often utilise colorimetric indicator substrates that
are readily detectable spectrophotometrically, many in the
visible wavelength range. Luminescent substrates could also
be used for increased sensitivity.

Hybridisable DNA segments may include any of a number of segments of the disclosed DNA. For example, relatively short 15 segments of at least 12 or so base pairs may be employed, or, more preferably when probes are desired, longer segments of at least 20, at least 30, and at least 40 base pairs, depending on the particular applications desired. Shorter segments are preferred as primers in molecular amplification tech-20 niques such as PCR, while some of the longer segments are generally preferable for blot hybridisations. It should be pointed out, however, that while sequences disclosed for the DNA segments of the present invention are defined by SEQ ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22, a certain amount of 25 variation or base substitution would be expected, e.g., as may be found in mutants or strain variants, but which do not significantly affect hybridisation characteristics. Such variations, including base modifications occurring naturally 30 or otherwise, are intended to be included within the scope of the present invention.

While the Bb OspH antigens of the present invention have been disclosed in terms of specific amino acid sequences SEQ ID NO: 19, SEQ ID NO: 21 and SEQ ID NO: 23, it is nonetheless contemplated that the amino acid sequences will be found to vary from species to species and isolate to isolate. More-

over, it is quite clear that changes may be made in the underlying amino acid sequence through e.g., site-directed mutagenesis of the DNA coding sequence, in a way that will not negate its antigenic capability.

The invention also relates to at least partially purified antigenic Bb proteins or polypeptides which are capable of producing an in vivo immunogenic response when challenged with Bb. These proteins may comprise all or part of the amino acid sequence encoded by the herein disclosed DNA. Particularly preferred antigenic proteins have the amino acid sequence shown in SEQ ID NO: 19, SEQ ID NO: 21 and SEQ ID NO: 23. These proteins as well as their epitopes will be useful in connection with vaccine development, and as antigen(s) in immunoassays for detection of Bb antibodies in biological fluids such as serum, seminal or vaginal fluids, urine, saliva, body exudates and the like.

In other aspects, the invention concerns recombinant vectors such as plasmids, phage or viruses, which comprise DNA segments in accordance with the invention, for use in replicating such sequences or even for the expression of encoded antigenic peptides or proteins. Vectors or plasmids may be used to transform a selected host cell. In preparing a suitable vector for transforming a cell, desired DNA segments from any of several Bb sources may be used, including genomic fragments, cDNA or synthetic DNA. In practice of the present invention, an expression vector may incorporate at least part of the DNA sequence of SEQ ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22, encoding one or more epitopic segments of the disclosed antigens of the present invention.

30 Expression vectors may be constructed to include any of the DNA segments hereinabove disclosed. Such DNA might encode an antigenic protein specific for virulent strains of Bb or even hybridisation probes for detecting Bb nucleic acids in samples. Longer or shorter DNA segments could be used, depending on the antigenic protein desired. Epitopic regions of

the disclosed proteins of the present invention expressed or encoded by the disclosed DNA could be included as relatively short segments of DNA. A wide variety of expression vectors are possible including, for example, DNA segments encoding reporter gene products useful for identification of heterologous gene products and/or resistance genes such as antibiotic resistance genes which may be useful in identifying transformed cells.

Recombinant vectors such as those described are particularly preferred for transforming bacterial host cells. Accordingly, a method is disclosed for preparing transformed bacterial host cells that includes generally the steps of selecting a suitable bacterial host cell, preparing a vector containing a desired DNA segment and transforming the selected bacterial host cell. Several types of bacterial host cells may be employed, including Bb, E. coli, B. subtilis, and the like as well as prokaryotic host cells.

Transformed cells may be selected using various techniques, including screening by differential hybridisation, differential display techniques, identification of fused reporter gene products, resistance markers, anti-antigen antibodies and the like. After identification of an appropriate clone, it may be selected and cultivated under conditions appropriate to the circumstances, as for example, conditions favouring expression or, when DNA is desired, replication conditions.

Another aspect of the invention involves the preparation of antibodies and vaccines from the antigenic OspH proteins or epitopic regions of these proteins encoded by the disclosed 30 DNA. It is expected that the sensitivity and specificity of antibody response to these OspH proteins and their epitopes will be superior to the response that has been obtained from other Bb antigens that are not associated with virulence. Previous work with several Bb antigens isolated from both virulent and avirulent strains indicated low sensitivity when

20

25

immunofluorescence and ELISA assays were employed, especially during early stages of infection.

In both immuno diagnostics and vaccine preparation, it is often possible and indeed more practical to prepare antigens 5 from segments of a known immunogenic protein or polypeptide. Certain epitopic regions may be used to produce responses similar to those produced by the entire antigenic polypeptide. Potential antigenic or immunogenic regions may be identified by any of a number of approaches, e.g., Jame-10 son-Wolf or Kyte-Doolittle antigenicity analyses or Hopp and Woods (1981) hydrophobicity analysis (see, e.g., Kyte and Doolittle, 1982, or U.S. Patent No. 4,554,101). Hydrophobicity analysis assigns average hydrophilicity values to each amino acid residue from these values average hydrophilicities can be calculated and regions of greatest hydrophilicity 15 determined. Using one or more of these methods, regions of predicted antigenicity may be derived from the amino acid sequence of the disclosed OspH polypeptides. Proposed epitopic regions from the disclosed OspH antigens include the 20 sequences corresponding to amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134 and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23.

25 Antigenic epitopes can also be determined using different experimental procedures known to the skilled person. For example, the DNA encoding the OspH polypeptides can be digested with restriction enzymes is such a manner that DNA fragments encoding specific parts of the OspH polypeptide are obtained. These DNA fragments can be expressed in a suitable expression system. The OspH polypeptide fragments obtained can be analyzed with monoclonal or polyclonal antibodies obtained by immunisation with the full length form of the OspH polypeptide or fragments thereof, or with Lyme disease patient sera to obtain information on immunogenicity and the presence of epitopes. Fragments found to be positive in such

a simple screening assay where they react specifically with 'e.g. polyclonals raised against OspH are thus suitable candidates for a multitude of the applications where full-length OspH would also be suitable.

- 5 A similar approach can be used where random mutations are introduced in the nucleotide sequence encoding OspH, and only the expression products which retain a suitable reactivity with e.g. OspH positive polyclonal antibodies will be used as candidates for further applications.
- 10 Peptide fragments for the identification of epitopes can also be obtained by synthetic methods. Suitable peptides can be synthesised based on the amino acid sequence of the OspH polypeptides, e.g. peptides with amino acid sequence identical to consecutive fragments from the N-terminus to the C-terminus of the OspH polypeptide can be synthesised on solid-phase media. Such custom made peptide libraries can be obtained from commercial sources.

Finally another way of simply identifying epitopes is to digest a polypeptide antigen with a known amino acid sequence with endo- and exopeptidases. The obtained fragments are tested against antibodies directed against the whole polypeptide, and by way of deduction, the precise location of the linear epitopes can be determined. A variation of this method involves the recombinant production of subfragments (cf. the above) of the full-length polypeptide followed by the same test procedure.

It is contemplated that the antigens and immunogens of the invention will be useful in providing the basis for one or more assays to detect antibodies against Bb. Previous assays have used whole Bb as the antigen. Sera from normal individuals not exposed to Bb often contain antibodies that react with Bb antigens, in particular antigens that have epitopes in common with other bacteria. It is necessary to adjust assay conditions or the diagnostic threshold of reactivity to

avoid false positive reactions due to these cross-reactive antibodies in normal sera. These adjustments may in turn decrease the sensitivity of the assay and lead to false negative reactions, particularly in the early stages of Bb infection. Assays using the disclosed OspH proteins or antigenic polypeptides thereof, are expected to give superior results both in sensitivity and selectivity when compared to assays that use whole Bb or even purified flagella in either an indirect ELISA or an antibody capture ELISA format. Western immunoblots based on reactions with such antigens (whole 10 Bb, flagella and the like) have been difficult to interpret due to the presence of antibodies in sera from unexposed individuals. These antibodies cross react with Bb antigens, most particularly the 41 kDa flagellin and the 60 kDa common antigen protein. Generally, assays which use whole organisms or purified flagella tend to contain antigens with epitopes that will cross react with other bacterial antigens. For example, the N and C terminal regions of the Bb flagellin possess 52-55% sequence identity with the Salmonella typhimurium and Bacillus subtilis sequences (Wallich et al., 1990), exemplifying the highly conserved nature of flagellin structure. The 60 kDa Bb protein is likewise 58% homologous with the E. coli protein (Shanafelt et al., 1991). Such cross reactivity is not likely with the disclosed OspH antigens, which are apparently unique to Bb. 25

It is further anticipated that recombinant derived OspH Bb proteins will be particularly preferred for detecting Bb infections. Unexposed individuals should have a low reactivity to one or more epitopes of the OspH proteins thereby making it possible to use lower dilutions of serum and increase sensitivity. Using a combination of more than one of these unique antigens may also enhance sensitivity without sacrificing specificity.

Preferred immunoassays are contemplated as including various types of enzyme linked immunoassays (ELISAs), immunoblot techniques, and the like, known in the art. However, it

readily appreciated that utility is not limited to such 'assays, and useful embodiments include RIAs and other non-enzyme linked antibody binding assays or procedures.

Yet another aspect of the invention is a method of detecting

Bb nucleic acid in a sample. The presence of Bb nucleic acid
in the sample may be indicated by the presence of the
polypeptide products which it encodes. The method therefore
includes detecting the presence of at least a portion of any
of the polypeptides herein disclosed. Suitable detection

methods include, for example, immuno detection reagents, PCR
amplification, and hybridisation.

Yet another aspect of the invention includes one or more primers capable of priming amplification of the disclosed DNA of SEQ ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22. Such primers are readily generated taking into account the base sequence of the DNA segment of SEQ ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22., the disclosed DNA, or deriving a base sequence from the amino acid sequence of a purified polypeptide encoded by the DNA. Primers are analogous to hybridisation probes, but are generally relatively short DNA segments, usually about 7-20 nucleotides.

Methods of diagnosing Lyme disease are also included in the invention. In one embodiment, an antibody-based method includes obtaining a sample from a patient suspected of having Lyme disease, exposing that sample to one or more epitopes of the Bb protein which is encoded by the DNA disclosed and finally determining a reactivity of the antibody with one or more epitopes of a Bb protein that may be in the sample. The reactivity measured is indicative of the presence of Lyme disease. Typical samples obtainable from a patient include human serum, plasma, whole blood, cerebrospinal fluid, seminal or vaginal fluids, exudates and the like.

Several variations of antibody-based methods are contemplated for development; for example, an indirect ELISA using the

OspH proteins or other Bb proteins as an antigen. The OspH proteins may be produced in large quantities by recombinant DNA vectors already disclosed and purified. Optimal concentration of the antigen could be determined by checker board titration and diagnostic potential of the OspH proteins assay examined further by testing serum from mice at different stages of infection and infected with different strains of Bb. These results could indicate the relative time course for sera conversion for each of the assays and would also show whether infection with different strains causes variation in anti- OspH protein titers.

Likewise, reactive epitopes of the OspH polypeptides are contemplated as useful either as antigens in an ELISA assay or to inhibit the reaction of antibodies toward intact OspH proteins bound to a well. Epitopic peptides could be generated by recombinant DNA techniques previously disclosed or by synthesis of peptides from individual amino acids. In either case, reaction with a given peptide would indicate presence of antibodies directed against one or more epitopes. In addition to its diagnostic potential, this method is seen as being particularly effective in characterising monoclonal antibodies against the OspH proteins and other virulence associated proteins.

In further aspects, the present invention concerns a kit for
the detection of Bb antigens, the kit including a protein or
peptide which includes an epitope thereof, together with
means for detecting a specific immunoreaction between an
antibody and its corresponding antigen. Examples of suitable
means include labels attached directly to the antigen or
antibody, a secondary antibody having specificity for human
Ig, or protein A or protein G. Alternatively, avidin-biotin
mediated Staphylococcus aureus binding could be used. For
example, the monoclonal antibody may be biotinylated so as to
react with avidin complexed with an enzyme or fluorescent
compound.

A particular kit embodiment of the invention concerns detection of antibodies against the described Bb OspH antigens, epitopes thereof as represented by portions of the amino acid sequences, or closely related proteins or peptides, such as 5 epitopes associated with other virulence-associated proteins detected by comparison of low-passage, virulent and highpassage, avirulent strains of Bb. The antigen for the kit(s) consists of the Bb OspH proteins or portions thereof produced by a recombinant DNA vector in E. coli or another bacterial 10 or non-bacterial host. Alternatively, the antigen may be purified directly from Bb or manufactured as a synthetic peptide. Samples for the assays may be body fluids or other tissue samples from humans or animals. The presence of reactive antibodies in the samples may be demonstrated by anti-15 body binding to antigen followed by detection of the antibody-antigen complex by any of a number of methods, including ELISA, RIA, fluorescence, agglutination or precipitation reactions, nephelometry, or any of these assays using avidinbiotin reactions. The degree of reactivity may be assessed by 20 comparison to control samples, and the degree of reactivity used as a measure of present or past infection with Bb. The assay(s) could also be used to monitor reactivity during the course of Lyme disease, e.g., to determine the efficacy of therapy.

In still further embodiments, the invention contemplates a kit for the detection of Bb nucleic acids in the sample, wherein the kit includes one or more nucleic acid probes specific for the ospH genes, together with means for detecting a specific hybridisation between such a probe and Bb nucleic acid, such as an associated label.

DETAILED DESCRIPTION OF THE INVENTION

Nucleic acid fragments of the invention

The present invention relates to the utility of Bb associated nucleic acid fragments as diagnostic or preventive tools in

5 Lyme disease as well as for the preparation of OspH and useful OspH analogues..

In a first aspect the present invention therefore relates to an isolated nucleic acid fragment which encodes a polypeptide fragment which exhibits a substantial immunological reactivity with a rabbit polyclonal antibody raised against a polypeptide having an apparent molecular weight of 13 kDa as determined by SDS-PAGE and subsequent visualization, said polypeptide being derived from Borrelia burgdorferi B313 and consisting of the amino acid sequence 1-167 of SEQ ID NO: 19, said rabbit polyclonal antibody exhibiting substantially no immunological reactivity with proteins from at least 95% of spirochaetes randomly selected from the group consisting of Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.

20 By the term "nucleic acid fragment" as used herein is meant a fragment of DNA or RNA, but also of PNA (cf. Nielsen P E et al., 1991), having a length of at least two joined nucleotides. It will be understood, that although the disclosed nucleic acid fragments of the present invention are DNA fragments, it may be desirable to employ an RNA fragment in e.g. a viral vector, the genome of which is natively composed of RNA. For the purposes of preparing e.g. probes for hybridization assays as described below, PNA fragments may prove useful, as these artificial nucleic acids have been demonstrated to exhibit very dynamic hybridization properties.

The term "a substantial immunological reactivity" is meant to designate a marked immunological binding between an anti-body/antiserum on the one hand, and on the other an antigen,

under well-defined conditions with respect to physicochemical parameters as well as concentrations of antigens and antibodies. Thus, a substantial immunological reactivity should be clearly distinguishable from a non-specific interaction between an antibody/antiserum and an antigen. This distinction can for instance be made by reacting the antibody/antiserum with a known concentration of an antigen which has previously been shown not to react with the antibody/antiserum, and then using this reaction as a negative 10 control. A positive control could suitably be the reaction between the antibody/antiserum and the same concentration of the antigen used for the immunisation resulting in the production of the antibody/antiserum. In such an assay, an antigen resulting in a relative signal of at least 10% (calculated as $\mathbf{S_m} \cdot (\mathbf{S_p \text{-}S_n}) \cdot \mathbf{100}\text{, where } \mathbf{S_m}$ is the measured signal, 15 $\mathbf{S}_{\mathbf{p}}$ the positive control signal, and $\mathbf{S}_{\mathbf{n}}$ the negative control signal) is regarded as having a substantial immunological reactivity. An antigen exhibiting "substantially no immunological reactivity" therefore is defined as an antigen giving a 20 signal of less than 10%.

By the terms "present" and "substantially absent", when referring to amino acid sequences and polypeptides in bacteria, are meant that the concentration of the amino acid sequence/polypeptide in a bacterium where it is "present" is at least 100 times higher than in a bacterium where it is substantially absent. However, it is preferred that the ratio of the concentrations are at least 1000, and more preferred at least 10,000, 100,000 or even higher. It is especially preferred that there can be observed no concentration of the amino acid sequence/polypeptide in the bacterium from where it is substantially absent.

Although the data presented herein demonstrate that there is no cross-reactivity between antigens from Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica and the disclosed polypeptides, it is conceivable that a few isolates of these bacteria will exhibit some cross-reacti-

30

35

vity. As can be deduced from the above it is expected that the cross-reactivity will be less than 5% (since there is no reactivity with at least 95% of randomly chosen Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica), and according to the invention this cross-reactivity may be even lower, such as at the most 4% and 3%, preferably at the most 2%, such as 1%. According to the invention the cross-reactivity is most preferred at most ½%, such as 0%. In such a case there will be no substantial immunological reactivity between the rabbit antiserum mentioned above and whole cell preparations of Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica.

When using the term "cross-reactivity" is herein meant the

phenomenon that two species exhibit a common feature which is
detected in a reaction. In the present context the term
cross-reactivity is used for similar reactions in antigenantibody interactions as well as in hybridization interactions. Hence, the above-cited considerations concerning

cross-reactivity of polypeptides apply for all cross-reactions between on the one hand the polypeptides/DNA fragments
of the invention and on the other hand material from Borrelia
hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia
hispanica; this is also true for the quantitative assessment
of whether cross-reactivity is present or not.

Nucleic acid fragments of the invention useful as hybridisation probes and/or primers are not necessarily those fragments encoding immunologically useful polypeptides. Therefore the invention also relates to nucleic acid fragments which hybridises readily under highly stringent hybridization conditions with a DNA fragment having a nucleotide sequence selected from the group consisting of SEQ ID NO: 18, SEQ ID NO: 20, and SEQ ID NO: 22, or with a DNA fragment complementary thereto, but exhibits no substantial hybridization when the hybridization conditions are highly stringent with genomic DNA from at least 95% of spirochaetes randomly

selected from the group consisting of Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica. The term "highly stringent" when used in conjunction with hybridisation conditions is as defined in the art, i.e. 5-10°C under the melting point T_m, cf. Sambrook et al, 1989, pages 11.45-11.49.

Interesting nucleic acid fragments of the invention encode a polypeptide fragment comprising an amino acid sequence comprised in a polypeptide, said polypeptide being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia 10 burgdorferi B313, Borrelia garinii IP90, and/or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica. It is preferred that said polypeptide is a protein having an apparent molecular weight of 13 kDa, and it is still more preferred that the encoded polypeptide fragment comprises at least one epitope (such as at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, or at least 25 epitopes) being present in whole cell preparations 20 of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica. This at least 25 one epitope is preferably one from a protein having an apparent molecular weight of 13 kDa.

By the terms "epitope" and "epitopic region" are meant the spatial part of an antigen responsible for the specific

30 binding to the antigen-binding part of an antibody. It goes without saying that the identification of epitopes of the disclosed antigens will facilitate the production of polypeptides which exhibit marked antigenicity thus making them interesting with respect to diagnosis of Borreliosis and vaccination against infections with Bb; identification of epitopes have been discussed above.

Preferred nucleic acid fragments of the invention are DNA fragments, especially those which have nucleotide sequences with a sequence identity of at least 70% with SEQ ID NO: 18, SEQ ID NO: 20, or SEQ ID NO: 22 or with subsequences thereof of at least 12 nucleotides. However, the degree of sequence identity may be even higher such as at least 75%, 80%, 85%, 87%, and 89%. It is preferred that the degree of sequence identity is at least 90%, such as 92%, 94% or 95%, and especially preferred are DNA fragments with a sequence identity of at least 96% with SEQ ID NO: 18, SEQ ID NO: 20, or SEQ ID 10 NO: 22. Especially for high accuracy hybridization assays, a total sequence identity is necessary, and therefore preferred. Other preferred nucleotide acid fragments of the invention are those which encode a polypeptide of the invention (cf. the below discussions concerning these polypeptides 15 and their degree of sequence identity with the amino acid sequences disclosed herein) which has an amino acid sequence exhibiting a sequence homology of at least 50% with SEQ ID NO: 19, SEQ ID NO: 21, or SEQ ID NO: 23 or with subsequences thereof having a length of at least 10 amino acid residues. 20 Also the sequence identity of the encoded polypeptide fragment is preferably higher, such as at least 60%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 92%, at least 94%, at least 95%, and at least 96%.

The term "identity" is, with respect to nucleotide fragments such as DNA fragments, intended to indicate the identity between the nucleotides in question between which the identity is to be established, in the match with respect to nucleotide composition and position in the DNA fragments.

With respect to polypeptides and fragments thereof described herein, the term means an identity between the amino acids in question between which the homology is to be established, in the match with respect to amino acid composition and their position in the polypeptides. The term "sequence identity" thus indicates a quantitative measure of the degree of homology between two amino acid sequences or between two nucleotide sequences of equal length: The sequence identity

can be calculated as $\frac{(N_{ref}-N_{dif})^{100}}{N_{ref}}$, wherein $N_{\mbox{dif}}$ is the total

number of non-identical residues in the two sequences when aligned and wherein $N_{\rm ref}$ is the number of residues in one of the sequences. Hence, the DNA sequence AGTCAGTC will have a sequence identity of 75% with the sequence AATCAATC ($N_{\rm dif}=2$ and $N_{\rm ref}=8$).

Considerations similar to those given above for the immunological reactivity and cross-reactivity of antigens can be applied for the distinction between a nucleic acid fragment which "hybridizes readily" and a fragment which "exhibits substantially no hybridization" under high stringency conditions; i.e. a nucleic acid which hybridizes readily should exhibit at least 10% of a true positive signal.

As discussed in the examples, putative epitopes have been identified in the OspH protein sequences. Therefore, especially preferred nucleic acid fragments of the invention are those comprising a sequence encoding a polypeptide which comprises at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134, and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23, all of which have been identified as putative epitopic regions.

25 Highly preferred nucleic acid fragments are those which encode full-length OspH, i.e. nucleic acid fragments which encode a protein having an apparent molecular weight of 13 kDa which is present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but which is substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica. Since this 13 kDa

protein has been demonstrated in fraction B of Bb, it is preferred that this encoded protein is present in fraction B from Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.

5 Analysis of the effects of exposure of whole Bb cells to proteinase K has now demonstrated that such Bb cells lose their reactivity with antibodies against the 13 kDa polypeptide and that fraction B of Bb cells are devoid of the 13 kDa protein. Hence, it must be concluded that OspH is a surface exposed polypeptide in Bb, and therefore preferred nucleic acid fragments are those which encode a surface exposed protein of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.

15 Very preferred embodiments of the nucleic acid fragments of the invention comprise a nucleotide sequence encoding a polypeptide fragment which includes an amino acid sequence selected from the group consisting of SEQ ID NOs: 19, 21, and 23, and of these, those which comprise a nucleotide sequence selected from the group consisting of SEQ ID NOs: 18, 20, and 22 are especially preferred. Most preferred nucleic acid fragments of the invention are those which consist of a nucleotide sequence encoding a polypeptide fragment consisting of an amino acid sequence selected from the group consisting of SEQ ID NOs: 19, 21, and 23, and the three most preferred are those which consist of the nucleotide sequence selected from the group consisting of SEQ ID NOs: 18, 20, and 22.

Analogues of the disclosed nucleic acid fragments which also form part of the invention are nucleic acid fragments which are fused to at least one other nucleic acid fragment which encodes a fusion partner. This fusion partner can be a protein enhancing the immunogenicity of the fused protein relative to a protein without the encoded fusion partner. Such encoded proteins may e.g. be lipoproteins, e.g. the outer

membrane lipoprotein from E. coli and OspA from Borrelia burgdorferi sensu lato; viral proteins, e.g. from Hepatitis B surface antigen, Hepatitis B core antigen, and the influenza virus non-structural protein NS1 (cf. EP-A-0 366 238 and WO 88/01875); immunoglobulin binding proteins, e.g. protein A, protein G, and the synthetic ZZ-peptide (cf. EP-A-0 243 333 and US 5,411,732); T-cell epitopes; or B-cell epitopes.

Other nucleic acid fragments to form part of a nucleic acid fragment of the invention encoding a fusion polypeptide are those encoding polypeptides which facilitates expression and/or purification of the fused peptide. Such encoded polypeptides could according to the invention be bacterial fimbrial proteins, e.g. the pilus components pilin and papA; protein A; the ZZ-peptide; the maltose binding protein; gluthatione S-transferase; β -galactosidase; calmodulin binding protein; or poly-histidine.

Of course, also fusion partners derived from OspH are interesting and these could be those which have the same amino acid sequence as at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135, and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134 and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133, and 161-165 in seq ID NO: 23

25 It will be understood from the above that various analogues and subsequences of the nucleic acids disclosed in the sequence listing herein are interesting aspects of the invention, as are nucleic acid fragments encoding fused polypeptides including polypeptides encoded by nucleic acid fragments of the invention.

The term "analogue" with regard to the nucleic acid fragments of the invention is intended to indicate a nucleotide sequence which encodes a polypeptide identical or substan-

tially identical to a polypeptide encoded by a nucleic acid fragment of the invention (SEQ ID NO's: 18, 20, and 22).

It is well known that the same amino acid may be encoded by various codons, the codon usage being related, inter alia, to 5 the preference of the organisms in question expressing the nucleotide sequence. Thus, one or more nucleotides or codons of a nucleic acid fragment of the invention may be exchanged by others which, when expressed, result in a polypeptide identical or substantially identical to the polypeptide encoded by the nucleic acid fragment in question.

Also, the term "analogue" is used in the present context to indicate a nucleic acid fragment or a nucleic acid sequence of a similar nucleotide composition or sequence as the nucleic acid sequence encoding the amino acid sequence having the immunological properties discussed above, allowing for 15 minor variations which do not have an adverse effect on the biological function and/or immunogenicity as compared to the disclosed polypeptides, or which give interesting and useful novel binding properties or biological functions and immunogenicities etc. of the analogue. The analogous nucleic acid fragment or nucleic acid sequence may be derived from an animal or a human or may be partially or completely of synthetic origin as described herein. The analogue may also be derived through the use of recombinant nucleic acid tech-25 niques.

Furthermore, the terms "analogue" and "subsequence" are intended to allow for variations in the sequence such as substitution, insertion (including introns), addition, deletion and rearrangement of one or more nucleotides, which 30 variations do not have any substantial effect on the polypeptide encoded by a nucleic acid fragment or a subsequence thereof. The term "substitution" is intended to mean the replacement of one or more nucleotides in the full nucleotide sequence with one or more different nucleotides, "addition" is understood to mean the addition of one or more nucleotides

35

at either end of the full nucleotide sequence, "insertion" is intended to mean the introduction of one or more nucleotides within the full nucleotide sequence, "deletion" is intended to indicate that one or more nucleotides have been deleted from the full nucleotide sequence whether at either end of the sequence or at any suitable point within it, and "rearrangement" is intended to mean that two or more nucleotide residues have been exchanged with each other.

Polypeptide fragments of the invention

The present invention relates to the utility of Bb associated antigenic proteins as diagnostic or preventive tools in Lyme disease. Proteins have been identified as associated only (or predominantly) with virulent isolates of Bb, providing a basis for several types of diagnostic tests for Lyme disease, including immuno diagnostic and nucleic acid identification, such as those based on amplification procedures. All these embodiments rely on the availability of the OspH proteins and their analogues.

Another part of the invention therefore pertains to a polypeptide fragment which exhibits a substantial immunologi-20 cal reactivity with a polyclonal rabbit antibody raised against a polypeptide having an apparent molecular weight of 13 kDa as determined by SDS PAGE, followed by visualization, and being derived from Borrelia burgdorferi B313, said polypeptide comprising the amino acid sequence 1-167 of SEQ ID NO: 19, said polyclonal rabbit antibody exhibiting substantially no immunological reactivity with whole cell preparations from at least 95% of randomly selected B. hermsii, B. crocidurae, B. anserina, or B. hispanica, with the proviso that said polypeptide is essentially free from other 30 Borrelia-derived antigens when it is identical in amino acid sequence to a 13 kDa surface exposed polypeptide which can be extracted from Borrelia burgdorferi sensu lato.

As mentioned above, the 13 kDa polypeptide has been identified in SDS gels earlier. However, the 13 kDa polypeptide has never been purified to homogeneity, let alone been cloned and sequenced. The present invention is therefore the first to provide the 13 kDa polypeptide in a form which is totally free from contaminating and potentially harmful (for e.g. vaccine purposes) Borrellia antigens, i.a. the 13 kDa polypeptide in a substantially pure form. The present invention is also the first to provide useful variants of the 13 kDa polypeptide (such variants including subsequences of the polypeptide as well as analogues wherein changes have been made to the native amino acid sequence). It should be noted that it is highly problematic if not impossible to purify the native 13 kDa antigen to homogeneity since it is a

lipoprotein; it is well-known to the skilled person in protein purification that lipidated proteins present special
problems, especially when it is à priori unknown that the
protein is indeed lipidated. However, upon the provision of
recombinant or synthetic OspH as disclosed herein, it has
become possible to readily prepare OspH in a form free of
other borrelia antigens and it has also become possible to
prepare variants of OspH which were not accessible without
access to knowledge of the genetic material encoding the
protein.

The polypeptide fragment of the invention is otherwise precisely as described above when discussing the nucleic acid fragments of the invention and all discussions pertaining to polypeptide fragments encoded by the nucleic acid fragments of the invention apply mutatis mutandis to the polypeptide fragments of the invention. Hence, all considerations regarding the presence or absence of the polypeptide fragments and their epitopes in various borrelial species as well as other considerations, apply for the polypeptide fragments of the invention.

35 Therefore, also analogues of the OspH polypeptides of the invention are embraced by the present invention. When using

the terms "analogue" and "subsequence" in connection with polypeptides is meant any polypeptide having the same immunological characteristics as the polypeptides of the invention described above with respect to the ability to confer an equivalent and increased resistance to infections with Borrelia burgdorferi sensu lato through immune responses against OspH. Thus, included is also a polypeptide from different sources, such as other bacteria or even from eukaryotic cells.

The terms "analogue" and "subsequence" with regard to a polypeptide of the invention are also used in the present context to indicate a protein or polypeptide of a similar amino acid composition or sequence as the characteristic amino acid sequence shown in SEQ ID NOs: 19, 21, and 23, allowing for minor variations which do not have an adverse effect on the ligand binding properties and/or biological function and/or immunogenicity, or which may give interesting and useful novel binding properties or biological functions and immunogenicities etc. The analogous polypeptide or protein may be derived from other microorganisms, cells, or animals and the analogue may also be derived through the use of recombinant DNA techniques as described herein

Furthermore, in the present context the term "immunologically equivalent" means that the analogue or subsequence of the polypeptide is functionally equivalent to the polypeptide with respect to the ability of evoking a protective immune response against Borrelia burgdorferi sensu lato infections.

The term "protective immune response" has its usual meaning, i.e. that the immune response evoked by the polypeptide in question protects the person immunized from contracting Lyme disease, or that the immune response evoked by the polypeptide at least confers a substantially increased resistance to infections with Borrelia burgdorferi sensu lato.

Finally, also fusion polypeptides as described above are part of the invention and this is also true for all considerations relating to fusion partners etc. which have been discussed above when dealing with the nucleic acid fragments of the invention.

Vectors, host cells and cell lines of the invention

Having provided the genetic information relating to the OspH proteins, the invention also allows for the preparation by means of genetic engineering of OspH and variants thereof.

10 Useful tools in this connection are cloning and expression vectors and therefore another important part of the invention is a non-borrelial vector carrying the nucleic acid fragment according to the invention and described in detail above. Such a vector of the invention is preferably capable of autonomous replication. Preferred vectors are selected from the group consisting of a plasmid, a phage, a cosmid, a minichromosome, and a virus.

Even though plasmid vectors are often preferred because of their relative ease of use, vectors which, when introduced in a host cell, are integrated in the host cell genome are especially preferred due to the increased stability of the obtained transformed cells.

In view of the discussion below, a preferred vector of the invention, comprises in the 5'→3' direction and in operable linkage, a promoter for driving expression of the nucleic acid fragment of the invention, a nucleic acid sequence encoding a leader peptide enabling secretion of or integration into the membrane of the polypeptide, the nucleic acid fragment according to the invention, and a nucleic acid sequence encoding a terminator. It is preferred that the promoter drives expression in a eukaryotic cell and also that the leader peptide enables secretion from or integration into the membrane of a mammalian cell.

5

The invention also relates to a transformed cell carrying the vector of the invention and capable of replicating the nucleic acid fragment according to the invention. Such a transformed cell is preferably a microorganism selected from a bacterium, a yeast, a protozoan, or a cell derived from a multicellular organism selected from a fungus, an insect cell, a plant cell, and a mammalian cell. Especially preferred host cells are bacteria of the genera Escherichia, Bacillus or Salmonella. E. coli is preferred.

10 For the purposes of production of recombinant OspH and variants thereof, a stable cell line is preferred and therefore the invention relates also to a stable cell line producing the polypeptide of the invention, which carries a vector of the invention, and which expresses the nucleic acid fragment of the invention.

In general, of course, prokaryotes are preferred for the initial cloning of DNA sequences and constructing the vectors useful in the invention. For example, in addition to the particular strains mentioned in the more specific disclosure below, one may mention by way of example, strains such as E. coli K12 strain 294 (ATCC No. 31446), E. coli B, and E. coli X 1776 (ATCC No. 31537). These examples are, of course, intended to be illustrative rather than limiting.

Prokaryotes are preferred for expression. The aforementioned strains, as well as *E. coli* W3110 (F-, lambda-, prototrophic, ATCC No. 273325), bacilli such as *Bacillus subtilis*, or other enterobacteriaceae such as *Salmonella typhimurium* or *Serratia marcesans*, and various *Pseudomonas* species may be used.

In general, plasmid vectors containing replicon and control
sequences which are derived from species compatible with the
host cell are used in connection with these hosts. The vector
ordinarily carries a replication site, as well as marking
sequences which are capable of providing phenotypic selection
in transformed cells. For example, E- coli is typically

transformed using pBR322, a plasmid derived from an E. coli species (see, e.g., Bolivar et al., 1977). The pBR322 plasmid contains genes for ampicillin and tetracycline resistance and thus provides easy means for identifying transformed cells.

5 The pBR plasmid, or other microbial plasmid or phage must also contain, or be modified to contain, promoters which can be used by the microorganism for expression.

Those promoters most commonly used in recombinant DNA construction include the β -lactamase (penicillinase) and lactose 10 promoter systems (Chang et al., 1978; Itakura et al. 1977; Goeddel et al., 1979) and a tryptophan (trp) promoter system (EPO Appl. Publ. No. 0036776). While these are the most commonly used, other microbial promoters have been discovered and utilised, and details concerning their nucleotide 15 sequences have been published, enabling a skilled worker to ligate them functionally with plasmid vectors (Siebenlist et al., 1980). Certain genes from prokaryotes may be expressed efficiently in E. coli from their own promoter sequences, precluding the need for addition of another promoter by 20 artificial means.

In addition to prokaryotes, eukaryotic microbes, such as yeast cultures may also be used. Saccharomyces cerevisiase, or common baker's yeast is the most commonly used among eukaryotic microorganisms, although a number of other strains are commonly available. For expression in Saccharomyces, the plasmid YRp7, for example, is commonly used (Stinchcomb et al., 1979; Kingsman et al., 1979; Tschumper et al., 1980). This plasmid already contains the trpl gene which provides a selection marker for a mutant strain of yeast lacking the ability to grow in tryptophan for example ATCC No. 44076 or PEP4-1 (Jones, 1977). The of the trpl lesion as a characteristic of the yeast host cell genome then provides an effective environment for detecting transformation by growth in the absence of tryptophan.

Suitable promoting sequences in yeast vectors include the promoters for 3-phosphoglycerate kinase (Hitzeman et al., 1980) or other glycolytic enzymes (Hess et al., 1968; Holland et al., 1978), such as enolase, glyceraldehyde-3-phosphate 5 dehydrogenase, hexokinase, pyruvate decarboxylase, phosphofructokinase, glucose-6-phosphate isomerase, 3-phosphoglycerate mutase, pyruvate kinase, triosephosphate isomerase, phosphoglucose isomerase, and glucokinase. In constructing suitable expression plasmids, the termination sequences associated with these genes are also ligated into the expression vector 3' of the sequence desired to be expressed to provide polyadenylation of the mRNA and termination.

Other promoters, which have the additional advantage of transcription controlled by growth conditions are the promo-15 ter region for alcohol dehydrogenase 2, isocytochrome C, acid phosphatase, degradative enzymes associated with nitrogen metabolism, and the aforementioned glyceraldehyde-3-phosphate dehydrogenase, and enzymes responsible for maltose and galactose utilisation. Any plasmid vector containing a yeastcompatible promoter, origin of replication and termination sequences is suitable.

In addition to microorganisms, cultures of cells derived from multicellular organisms may also be used as hosts. In principle, any such cell culture is workable, whether from vertebrate or invertebrate culture. However, interest has been 25 greatest in vertebrate cells, and propagation of vertebrate in culture (tissue culture) has become a routine procedure in recent years. Examples of such useful host cell lines are VERO and HeLa cells, Chinese hamster ovary (CHO) cell lines, and W138, BHK, COS-7 293 and MDCK cell lines.

Expression vectors for such cells ordinarily include (if necessary) an origin of replication, a promoter located in front of the gene to be expressed, along with any necessary ribosome binding sites, RNA splice sites, polyadenylation site, and transcriptional terminator sequences.

20

30

For use in mammalian cells, the control functions on the expression vectors are often provided by viral material. For example, commonly used promoters are derived from polyoma, Adenovirus 2, and most frequently Simian Virus 40 (SV40). The 5 early and late promoters of SV40 virus are particularly useful because both are obtained easily from the virus as a fragment which also contains the SV40 viral origin of replication (Fiers et al., 1978). Smaller or larger SV40 fragments may also be used, provided there is included the approximate-10 ly 250 bp sequence extending from the HindIII site toward the BglI site located in the viral origin of replication. Further, it is also possible, and often desirable, to utilise promoter or control sequences normally associated with the desired gene sequence, provided such control sequences are compatible with the host cell systems. 15

An origin of replication may be provided either by construction of the vector to include an exogenous origin, such as may be derived from SV40 or other viral (e.g., Polyoma, Adeno, VSV, BPV) or may be provided by the host cell chromosomal replication mechanism. If the vector is integrated into the host cell chromosome, the latter is often sufficient.

Methods of producing the polypeptides of the invention, such methods themselves being part of the invention thus comprise 25 the following steps:

- culturing a transformed cell or a stable cell line according of the invention under conditions facilitating the expression of the polypeptide by the cell or cell line, and
- 30 harvesting the polypeptide, and optionally subjecting the polypeptide to post-translational modification(s);

or, alternatively,

 synthesising the polypeptide by solid-phase peptide synthesis or by liquid-phase peptide synthesis.

The latter approach is with the present technology preferred when the polypeptide fragment is relatively short, but of course it cannot be excluded that these techniques will ultimately be refined so as to allow economically feasible production of longer fragments.

The need for post-translational modifications exists because certain polypeptides are prepared in the above-described 10 manner lacking for instance a fatty-acylation of an amino acid residue, or the polypeptide have for some reason been prepared in an elongated version which should be cleaved before the polypeptide will prove functional. The optional post-translational modifications thus preferably involve lipidation or glycosylation when these modifications have not 15 been accomplished by means of the preparative procedure itself. Applicable methods for accomplishing lipidation and/or glycosylation are well-known to the skilled person. Other post-translational modifications includes cleavage or elongation of the obtained product. In some instances, the 20 host cell or cell line also processes the translation product so as to obtain a processed polypeptide.

Preparation of useful variants of OspH

The present invention has addressed the cloning of nucleic acids encoding certain antigenic polypeptides related to the OspH proteins.

A method of preparing variants of the OspH antigens is sitedirected mutagenesis. This technique is useful in the preparation of individual peptides, or biologically functional 30 equivalent proteins or peptides, derived from the OspH antigen sequences, through specific mutagenesis of the underlying DNA. The technique further provides a ready ability to prepare and test sequence variants, for example, incorpora-

ting one or more of the foregoing considerations, by introducing one or more nucleotide sequence changes into the DNA. Site-specific mutagenesis allows the production of mutants through the use of specific oligonucleotide sequences which encode the DNA sequence of the desired mutation, as well as a sufficient number of adjacent nucleotides, to provide a primer sequence of sufficient size and sequence complexity to form a stable duplex on both sides of the deletion junction being traversed. Typically, a primer of about 17 to 25 nucle-10 otides in length is preferred, with about 5 to 10 residues on both sides of the junction of the sequence being altered.

In general, the technique of site-specific mutagenesis is well known in the art as exemplified by publications (Adelman et al., 1983). As will be appreciated, the technique typically employs a phage vector which exists in both a single 15 stranded and double stranded form. Typical vectors useful in site-directed mutagenesis include vectors such as the M13 phage (Messing et al., 1981). These phage are readily commercially available and their use is generally well known to those skilled in the art. 20

In general, site-directed mutagenesis in accordance herewith is performed by first obtaining a single-stranded vector which includes within its sequence a DNA sequence which encodes the OspH antigens. An oligonucleotide primer bearing the desired mutated sequence is prepared, generally synthetically, for example by the method of Crea et al. (1978). This primer is then annealed with the single-stranded vector, and subjected to DNA polymerising enzymes such as E. coli polymerase I Klenow fragment, in order to complete the synthesis of 30 the mutation-bearing strand. Thus, a heteroduplex is formed wherein one strand encodes the original non-mutated sequence and the second strand bears the desired mutation. This heteroduplex vector is then used to transform appropriate cells, such as E. coli cells, and clones are selected which include recombinant vectors bearing the mutated sequence arrangement. 35

. 25

The preparation of sequence variants of the selected ospH genes using site-directed mutagenesis is provided as a means of producing potentially useful species of the ospH genes and is not meant to be limiting as there are other ways in which sequence variants of the ospH genes may be obtained. For example, recombinant vectors comprising the desired OspH genes may be treated with mutagenic agents to obtain sequence variants (see, e.g., a method described by Eichenlaub, 1979) for the mutagenesis of plasmid DNA using hydroxylamine.

10 Vaccine Preparation and Use

Part of the present invention contemplates vaccine preparation and use. General concepts related to methods of preparation and use are discussed as applicable to preparations and formulations with the disclosed OspH antigens, its epitopes and subfragments thereof. In general, a vaccine of the invention comprises an amount of a polypeptide of the invention or produced according to the invention, said amount being effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being, the polypeptide being formulated in 20 combination with a pharmaceutically acceptable carrier, diluent or vehicle and the vaccine optionally further comprising an adjuvant. Further, the vaccine is generally used in a method of immunizing an animal, including a human being against infections with Borrelia burgdorferi sensu lato, the 25 method comprising administering to the animal an immunogenically effective amount of the vaccine to the animal.

Preparation of vaccines which contain peptide sequences as active ingredients is generally well understood in the art, as exemplified by U.S. Patents 4,608,251; 4,601,903; 4,599,231; 4,599,230; 4,596,792; and 4,578,770, all incorporated herein by reference. In general terms, the preparation of the vaccines of the invention is accomplished by admixing

- a polypeptide of the invention or prepared by the method thereof, and
- a pharmaceutically carrier, vehicle, or diluent, and optionally
- 5 an adjuvant.

Typically, such vaccines are prepared as injectables either as liquid solutions or suspensions; solid forms suitable for solution in, or suspension in, liquid prior to injection may also be prepared. The preparation may also be emulsified. The active immunogenic ingredient is often mixed with excipients which are pharmaceutically acceptable and compatible with the active ingredient. Suitable excipients are, for example, water, saline, dextrose, glycerol, ethanol, or the like, and combinations thereof. In addition, if desired, the vaccine

15 may contain minor amounts of auxiliary substances such as wetting or emulsifying agents, pH buffering agents, or adjuvants which enhance the effectiveness of the vaccines.

Suitable carriers are selected from the group consisting of a polymer to which the polypeptide(s) is/are bound by

20 hydrophobic non-covalent interaction, such as a plastic, e.g. polystyrene, or a polymer to which the polypeptide(s) is/are covalently bound, such as a polysaccharide, or a polypeptide, e.g. bovine serum albumin, ovalbumin or keyhole limpet haemocyanin. Suitable vehicles are selected from the group

25 consisting of a diluent and a suspending agent.

The vaccines are conventionally administered parenterally, by injection, for example, either subcutaneously or intramuscularly. Additional formulations which are suitable for other modes of administration include suppositories and, in some cases, oral formulations. For suppositories, traditional binders and carriers may include, for example, polyalkalene glycols or triglycerides; such suppositories may be formed from mixtures containing the active ingredient in the range

of 0.5% to 10%, preferably 1-2%. Oral formulations include such normally employed excipients as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, and the like. These compositions take the form of solutions, suspensions, tablets, pills, capsules, sustained release formulations or powders and contain 10-95% of active ingredient, preferably 25-70%.

The proteins may be formulated into the vaccine as neutral or salt forms. Pharmaceutically acceptable salts include acid addition salts (formed with the free amino groups of the peptide) and which are formed with inorganic acids such as, for example, hydrochloric or phosphoric acids, or such organic acids as acetic oxalic, tartaric, mandelic, and the like. Salts formed with the free carboxyl groups may also be derived from inorganic bases such as, for example, sodium, potassium, ammonium, calcium, or ferric hydroxides, and such organic bases as isopropylamine, trimethylamine, 2-ethylamino ethanol, histidine, procaine, and the like.

The vaccines are administered in a manner compatible with the 20 dosage formulation, and in such amount as will be therapeutically effective and immunogenic. The quantity to be administered depends on the subject to be treated, including, e.g., the capacity of the individual's immune system to synthesise antibodies, and the degree of protection desired. Precise 25 amounts of active ingredient required to be administered depend on the judgement of the practitioner. However, suitable dosage ranges are of the order of several hundred micrograms active ingredient per vaccination. For example, suitable dosages can be in the range 1-1000 μg , such as 30 between 2 and 750 μ g, between 5 and 500 μ g, between 7,5 and 250 μg , between 10 and 150 μg , between 10 and 100 μg , between 10 and 75 μ g, and between 10 and 50 μ g. Suitable regimes for initial administration and booster shots are also variable but are typified by an initial administration followed by 35 subsequent inoculations or other administrations.

The manner of application may be varied widely. Any of the conventional methods for administration of a vaccine are applicable. These are believed to include oral application on a solid physiologically acceptable base or in a physiologically acceptable base or in a physiologically acceptable dispersion, parenterally, by injection or the like. The dosage of the vaccine will depend on the route of administration and will vary according to the size of the host.

Various methods of achieving adjuvant effect for the vaccine include use of agents such as aluminium hydroxide or phos-10 phate (alum), commonly used as 0.05 to 0.1 percent solution in phosphate buffered saline, admixture with synthetic polymers of sugars (Carbopol) used as 0.25 percent solution, aggregation of the protein in the vaccine by heat treatment with temperatures ranging between 70° to 101°C for 30 second 15 to 2 minute periods respectively. Aggregation by reactivating with pepsin treated (Fab) antibodies to albumin, mixture with bacterial cells such as C. parvum or endotoxins or lipopolysaccharide components of gram negative bacteria, emulsion in 20 physiologically acceptable oil vehicles such as mannide monooleate (Aracel A) or emulsion with 20 percent solution of a perfluorocarbon (Fluosol-DA) used as a block substitute may also be employed. The adjuvant is preferably selected from the group consisting of dimethyldioctadecylammonium bromide (DDA), Quil A, poly I:C, Freund's incomplete adjuvant, IFN- γ , 25 IL-2, IL-12, monophosphoryl lipid A (MPL), and muramyl dipeptide (MDP).

In many instances, it will be desirable to have multiple administrations of the vaccine, usually not exceeding six vaccinations, more usually not exceeding four vaccinations and preferably one or more, usually at least about three vaccinations. The vaccinations will normally be at from two to twelve week intervals, more usually from three to five week intervals. Periodic boosters at intervals of 1-5 years, usually three years, will be desirable to maintain levels of the antibodies. The course of the immunisation may be fol-

lowed 26 by assays for antibodies for the supernatant antigens. The assays may be performed by labelling with conventional labels, such as radionuclides, enzymes, fluorescers, and the like. These techniques are well known and may be found in a wide variety of patents, such as U.S. Patent Nos. 3,791,932; 4,174,384 and 3,949,064, as illustrative of these types of assays.

The polypeptide of the invention can also be part of a multicomponent or combination vaccine, which is also an important part of the invention. Such a vaccine contains

an amount of the polypeptide fragment of the invention or of a polypeptide fragment prepared according to the invention, the amount of the polypeptide fragment being effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being; and

at least one further Borrelia antigen,

the polypeptide fragment and the antigen being formulated in combination with a pharmaceutically acceptable carrier,

20 vehicle, or diluent and the vaccine optionally further comprising an adjuvant. All components of such a vaccine apart form the at least one further Borrelia antigen are as described in detail herein. With respect to the at least one further Borrelia antigen, it is preferred that it is selected from the group consisting of OspA, OspB, OspC, OspD, OspE, OspF, OspG, PC, Oms28, Oms45, Oms 66, decorin binding protein (dbp), LpLA7, EppA, T5, S1, 26 kDa, 39 kDa, 66 kDa, 79 kDa, 85 kDa, and 110 kDa antigen.

Another variant of a combination vaccine of the invention comprises at least two non-identical polypeptide fragments of the present invention or at least two non-identical polypeptide fragments prepared by the method of the invention, the vaccine comprising an amount of the polypeptides

effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being, in combination with a pharmaceutically acceptable carrier, vehicle, or diluent, the vaccine optionally further comprising an adjuvant. Also in this case, all components of the vaccine have been described elsewhere herein.

Another known way of achieving a suitable immune response in a vaccinated animal is by employing a so-called live vaccine,

i.a. this triggers both a B- and a T-cell mediated immune response, and therefore the invention also pertains to such a vaccine comprising a non-pathogenic microorganism carrying and being capable of expressing the nucleic acid fragment of the invention so as to produce the polypeptide of the invention, the live vaccine being effective in conferring increased resistance to infection with Borrelia burgdorferi sensu lato in an animal, including a human being. Preferred non-pathogenic microorganisms are selected from the group consisting of Mycobacterium bovis BCG, Salmonella typhi,

Salmonella typhimurium, Salmonella paratyphi, Staphylococcus aureus, and Listeria monocytogenes.

DNA vaccination

The invention also contemplates the use of disclosed nucleic acid segments in the construction of expression vectors or plasmids and use in host cells with a view to vaccination of the individual housing the host cells. Hence, the invention also pertains to a vaccine comprising a nucleic acid fragment or a vector of the invention, the vaccine effecting in vivo expression of antigens by an animal, including a human being, to whom the vaccine has been administered, the amount of expressed antigens being effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being. The related vaccination method consists of administering an amount of this vaccine which is effective to confer upon the mammal to

which it has been administered, an increased resistance to such infections.

The following is a general discussion relating to such use of nucleic acid fragments and the particular considerations in practising this aspect of the invention.

Direct injection of plasmid DNA has become a simple and effective method of vaccination against a variety of infectious diseases (see, e.g., Ulmer et al. 1993). It is potentially more potent and longer lasting than recombinant protein vaccination because it elicits both a humoral as well as a cellular immune response.

The present invention also provides for a DNA-based vaccine or immunological composition against Lyme disease (e.g., Borrelia burgdorferi, afzelii, or garinii) and can elicit an immunological response, which can confer protection, even up to 100%, in mice against challenge with an infectious strain of Borrelia burgdorferi. An exemplary plasmid of the invention contains the human cytomegalovirus immediate early promoter driving expression of the OspH protein. To facilitate expression in eukaryotic cells, the natural leader sequence of the gene encoding OspH has been replaced with the human tissue plasminogen activator leader sequence.

Protection can be demonstrated in mice by injecting, intramuscularly, naked plasmid DNA and subsequently challenging 25 with Bb spirochaetes. Sera following vaccination will contain high titers of antibody to OspH which will inhibit spirochete growth in vitro.

Thus, a DNA vaccine or immunological composition, expressing an OspH antigen, from Borrelia burgdorferi, Borrelia afzelii or Borrelia garinii or any combination thereof, can protect mice against infection by a Borrelia genospecies, the etiologic agent of Lyme disease. The composition is thus useful for eliciting a protective response in a host suscep-

tible to Lyme Disease, as well as for eliciting antigens and antibodies, which also are useful in and of themselves.

Therefore, as discussed above, the invention general sense preferably provides methods for immunising, or vaccinating, or eliciting an immunological response in a host, such as a host susceptible to Lyme disease, e.g., a mammalian host, against Borrelia and accordingly Lyme Disease, by administering DNA encoding an OspH antigen, for instance DNA encoding OspH from Borrelia burgdorferi, Borrelia afzelii, Borrelia garinii antigen or combinations thereof, in a suitable carrier or diluent, such as saline; and, the invention provides plasmids and compositions for performing the method, as well as methods for making the plasmids, and uses for the expression products of the plasmids, as well as for antibodies elicited thereby.

From present dog and human trials based on efficacy studies with mice (Erdile et al., 1993; USSN 08/373,455), it is clear that mice are now a suitable animal model with respect to Borrelia and Lyme disease for extrapolation to domestic animals, humans, and other animals susceptible to Lyme disease or Borrelia infection (e.g., wild animals such as deer).

In the present invention, the DNA encoding OspH or immunologically active fragment thereof, can be administered in dosages and by techniques well known to those skilled in the medical or veterinary arts taking into consideration such factors as the age, sex, weight, species and condition of the particular patient, and the route of administration. DNA encoding OspH or immunologically active fragment thereof, can be administered alone, or can be co-administered or sequentially administered with other Bb antigens, or with DNA encoding other Bb antigens; and, the DNA encoding OspH or immunologically active fragment thereof, can be sequentially administered, e.g., each spring as the "Lyme Disease season" is about to begin.

20

As broadly discussed above, the invention also pertains to plasmids comprising DNA including OspH encoding DNA for expression by eukaryotic cells. The DNA, from upstream to downstream (5' to 3'), can comprise: DNA encoding a promoter for driving expression in eukaryotic cells, DNA encoding a leader peptide which enables secretion of a prokaryotic protein sequence from a mammalian cell, DNA encoding an OspH antigen (or antigens) or immunologically active fragment thereof, DNA encoding other Bb antigens such as OspA, OspB, OspC or OspD or immunologically active fragment thereof, and DNA encoding a terminator.

For instance, the promoter can be a eukaryotic viral promoter such as a herpes virus promoter, e.g., human cytomegalovirus promoter DNA.

The DNA encoding a leader peptide which enables secretion of a prokaryotic protein sequence from a mammalian cell is any DNA encoding any suitable leader for this purpose such as DNA encoding a eukaryotic, preferably mammalian, leader sequence; for instance, DNA encoding a leader peptide of a peptide

10 hormone, or, for example, of insulin, renin, Factor VIII, TPA, and the like, with DNA encoding human tissue plasminogen activator (TPA) leader peptide presently preferred.

The human cytomegalovirus promoter can be an immediate early human cytomegalovirus promoter such as HCMV-IE. As to HCMV promoter, reference is made to U.S. Patents Nos. 5,168,062 and 5,385,839. The plasmid of the invention can contain the HCMV-IE gene 5' untranslated region (UTR) which includes Intron A. This sequence can be 3' to the HCMV-IE promoter and 5' to the activator portion of the 5' UTR sequence and leader peptide. The TPA sequence can be derived from the TPA gene and can encode a portion of the 5' UTR and leader peptide from that gene. The 5' UTR of TPA may increase eukaryotic cell expression.

The transcriptional terminator sequence can be any suitable terminator, such as a eukaryotic terminator, for instance, DNA encoding a terminator for a mammalian peptide, with the BGH terminator presently preferred.

5 The plasmid can be in admixture with any suitable carrier, diluent or excipient such as sterile water, physiological saline, and the like. Of course, the carrier, diluent or excipient should not disrupt or damage the plasmid DNA.

The plasmid can be administered in any suitable manner. The plasmid can be in a composition suitable for the manner of administration. The compositions can include: liquid preparations for orifice, e.g., oral, nasal, anal, vaginal, peroral, intragastric administration and the like, such as solutions, suspensions, syrups, elixirs; and liquid preparations for parenteral, subcutaneous, intradermal, intramuscular, intravenous administration, and the like, such as sterile solutions, suspensions or emulsions, e.g., for administration by injection. Intramuscular administration and compositions therefor are presently preferred.

The plasmids of the invention can be used for in vitro expression of antigens by eukaryotic cells. Recovery of such antigens can be by any suitable techniques; for instance, techniques analogous to the recovery techniques employed in the documents cited herein (such as the applications cited under Related Applications and the documents cited therein).

The thus expressed antigens can be used in immunological, antigenic or vaccine compositions, with or without an immunogenicity-enhancing adjuvant ("expressed antigen compositions"). Such compositions can be administered in dosages and by techniques well known to those skilled in the medical or veterinary arts taking into consideration such factors as age, sex, weight, species, condition of the particular patient, and the route of administration. These compositions can be administered alone or with other compositions, and can

be sequentially administered, e.g., each spring as the "Lyme bisease season" is about to begin.

The route of administration for the expressed antigen compositions can be oral, nasal, anal, ,vaginal, peroral, intragastric, parenteral, subcutaneous, intradermal, intramuscular, intravenous, and the like.

The expressed antigen compositions can be solutions, suspensions, emulsions, syrups,, elixirs, capsules (including "gelcaps" -gelatin capsule containing a liquid antigen or 10 fragment thereof preparation), tablets, hard-candy-like preparations, and the like. The expressed antigen compositions may contain a suitable carrier, diluent, or excipient such as sterile water, physiological saline, glucose or the like. The compositions can also be lyophilised. The compositions can contain auxiliary substances such as wetting or emulsifying agents, pH buffering agents, adjuvants, gelling or viscosity enhancing additives, preservatives, flavouring agents, colours, and the like, depending upon the route of administration and the preparation desired. Standard texts, such as "REMINGTON'S PHARMACEUTICAL SCIENCE", 17th edition, 1985, incorporated herein by reference, may be consulted to prepare suitable preparations, without undue experimentation.

Suitable dosages for plasmid compositions and for expressed antigen compositions can also be based upon the examples below, and upon the documents herein cited. For example, suitable dosages can be in the range 1-1000 μ g, such as between 2 and 750 μ g, between 5 and 500 μ g, between 7,5 and 250 μ g, between 10 and 150 μ g, between 10 and 100 μ g, between 10 and 75 μ g, and between 10 and 50 μ g, in expressed antigen compositions. In plasmid compositions, the dosage should be a sufficient amount of plasmid to elicit a response analogous to the expressed antigen compositions; or expression analogous to dosages in expressed antigen compositions. For

instance, suitable quantities of plasmid DNA in plasmid compositions can be 0.1 to 2 mg, preferably 1-10 $\mu \rm g$.

Thus, in a broad sense, the invention further provides a method comprising administering a composition containing

5 plasmid DNA including DNA encoding an OspH antigen or antigens: for expression of the antigen or antigens in vivo for eliciting an immunological, antigenic or vaccine (protective) response by a eukaryotic cell; or, for ex vivo or in vitro expression (That is, the cell can be a cell of a host susceptible to Lyme Disease, i.e., the administering can be to a host susceptible to Lyme Disease such as a mammal, e.g., a human; or, the cell can be an ex vivo or in vitro cell). The invention further provides a composition containing an OspH antigen or antigens from expression of the plasmid DNA by a eukaryotic cell, in vitro or ex vivo, and methods for administering such compositions to a host mammal susceptible to Lyme disease to elicit a response.

Since the methods can stimulate an immune or immunological response, the inventive methods can be used for merely stimulating an immune response (as opposed to also being a protective response) because the resultant antibodies (without protection) are nonetheless useful. From eliciting antibodies, by techniques well-known in the art, monoclonal antibodies can be prepared and, those monoclonal antibodies, can be employed in well known antibody binding assays, diagnostic kits or tests to determine the presence or absence of an OspH antigen or to determine whether an immune response to the bacteria has simply been stimulated. Those monoclonal antibodies can also be employed in recovery or testing procedures, for instance, in immunoadsorption chromatography to recover or isolate an OspH antigen.

To prepare the inventive plasmids, the DNA therein is preferably ligated together to form a plasmid. For instance, the promoter, leader sequence, antigen and terminator DNA is preferably isolated, purified and ligated together in a 5' to

3' upstream to downstream orientation. A three-way ligation, as exemplified below, is presently preferred.

Nucleic Acid Hybridisation Embodiments

Also contemplated within the scope of the present invention is the use of the disclosed DNA as a hybridisation probe. While particular examples are provided to illustrate such use, the following provides general background for hybridisation applications taking advantage of the disclosed nucleic acid sequences of the invention.

As mentioned, in certain aspects, the DNA sequence informa-10 tion provided by the invention allows for the preparation of relatively short DNA (or RNA) sequences having the ability to specifically hybridise to Bb gene sequences. In these aspects, nucleic acid probes of an appropriate length are prepared based on a consideration of the sequence, e.g., SEQ 15 ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22 or derived from flanking regions of these genes. The ability of such nucleic acid probes to specifically hybridise to the Bb gene sequences lend them particular utility in a variety of embo-20 diments. Most importantly, the probes can be used in a variety of diagnostic assays for detecting the presence of pathogenic organisms in a given sample. However, either uses are envisioned, including the use of the sequence information for the preparation of mutant species primers, or primers for use in preparing other genetic constructs. 25

To provide certain of the advantages in accordance with the invention, the preferred nucleic acid sequence employed for hybridisation studies or assays includes sequences that are complementary to at least a 10 to 40, or so, nucleotide stretch of the selected sequence, such as that shown in SEQ ID NO: 18, SEQ ID NO: 20 and SEQ ID NO: 22. A size of at least 10 nucleotides in length helps to ensure that the fragment will be of sufficient length to form a duplex molecule that is both stable and selective. Molecules having

in length are generally preferred, though, in order to increase stability and selectivity of the hybrid, and thereby improve the quality and degree of specific hybrid molecules obtained. Thus, one will generally prefer to design nucleic acid molecules having gene-complementary stretches of 15 to 20 nucleotides, or even longer where desired. Such fragments may be readily prepared by, for example, directly synthesising the fragment by chemical means, by application of nucleic acid reproduction technology, such as the PCR technology of U.S. Patent 4,603,102, or by introducing selected sequences into recombinant vectors for recombinant production.

The present invention will find particular utility as the
basis for diagnostic hybridisation assays for detecting Bbspecific RNA or DNA in clinical samples. Exemplary clinical
samples that can be used in the diagnosis of infections are
thus any samples which could possibly include nucleic acid,
including samples from tissue, blood serum, urine or the
like. A variety of tissue hybridisation techniques and systems are known which can be used in connection with the
hybridisation aspects of the invention, including diagnostic
assays such as those described in Falkow et al., U.S. Patent
4,358,535.

25 Accordingly, the nucleotide sequences of the invention are important for their ability to selectively form duplex molecules with complementary stretches of Bb gene segments. Depending on the application envisioned, one will desire to employ varying conditions of hybridisation to achieve varying degree of selectivity of the probe toward the target sequence. For applications requiring a high degree of selectivity, one will typically desire to employ relatively stringent conditions to form the hybrids, for example, one will select relatively low salt and/or high temperature conditions, such as provided by 0.02M-0.15M NaCl at temperatures of 50°C to 70°C. These conditions are particularly selective,

and tolerate little, if any, mismatch between the probe and the template or target strand.

Of course, for some applications, for example, where one desires to prepare mutants employing a mutant primer strand 5 hybridised to an underlying template, less stringent hybridisation conditions are called for in order to allow formation of the heteroduplex. In these circumstances, one would desire to employ conditions such as 0.15 M-0.9 M salt, at temperatures ranging from 20°C to 55°C. In any case, it is generally appreciated that conditions can be rendered more stringent by the addition of increasing amounts of formamide, which serves to destabilise the hybrid duplex in the same manner as increased temperature. Thus, hybridisation conditions can be readily manipulated, and thus will generally be a method of choice depending on the desired results. 15

In clinical diagnostic embodiments, nucleic acid sequences of the present invention are used in combination with an appropriate means, such as a label, for determining hybridisation. A wide variety of appropriate indicator means are known in the art, including radioactive, enzymatic or other ligands, such as avidin/biotin, which are capable of giving a detectable signal. In preferred diagnostic embodiments, one will likely desire to employ an enzyme tag such as alkaline phosphatase or peroxidase, instead of radioactive or other environmentally undesirable reagents. In the case of enzyme tags, colorimetric indicator substrates are known which employed to provide a means visible to the human eye or spectrophotometrically, to identify specific hybridisation with pathogen nucleic acid-containing samples. Luminescent 30 substrates, which give off light upon enzymatic degradation, could also be employed and may provide increased sensitivity.

In general, it is envisioned that the hybridisation probes described herein will be useful both as reagents in solution hybridisation as well as in embodiments employing a solid phase. In embodiments involving a solid phase, the test DNA

(or RNA) from suspected clinical samples, such as exudates, body fluids (e.g., amniotic fluid cerebrospinal fluid) or even tissues, is adsorbed or otherwise affixed to a selected matrix or surface. This fixed, single-stranded nucleic acid is then subjected to specific hybridisation with selected probes under desired conditions. The selected conditions will depend on the particular circumstances based on the particular criteria required (depending, for example, on the G+C contents, type of target nucleic acid, source of nucleic acid, size of hybridisation probe, etc.). Following washing of the hybridised surface so as to remove non-specifically bound probe molecules, specific hybridisation is detected, or even quantified, by means of the label.

The invention has disclosed a DNA segment encoding an
antigenic Bb protein. Detection of that DNA or various parts
thereof is expected to provide the basis for a useful amplification assay. One method of detecting the OspH antigen
genes is based on selective amplification of known portions
of the gene. A particular method utilises PCR amplification,
using any one of a number of primers that could be prepared
from knowledge of the nucleic acid sequence of SEQ ID NO: 18,
SEQ ID NO: 20 and SEQ ID NO: 22. Generally, such primers are
relatively short, e.g., 7-28 base pairs in length, and may be
derived from the respective sense or anti-sense strands of
the disclosed DNA segment. Synthesis of these primers may
utilise standard phosphoramidite chemistry (Beaucage et al.,
1981).

In summary, this part of the invention relates to a diagnostic composition adapted for the determination of Borrelia burgdorferi sensu lato in a sample the composition comprising an amount of the nucleic acid fragment of the invention which is effective to detectably bind to a nucleic acid fragment from Borrelia burgdorferi sensu lato present in the sample, the composition optionally comprising a detectable label.

Further, also an embodiment of the invention is a method of determining the presence of Borrelia burgdorferi sensu lato nucleic acids in a sample, comprising incubating the sample with the nucleic acid fragment of the invention, and detecting the presence of hybridized nucleic acids resulting from the incubation. Alternatively, such a method comprises subjecting the nucleic acid fragment of the invention to a molecular amplification reaction, such as PCR, and detecting the presence of amplified nucleic acid which is specific for Borrelia burgdorferi sensu lato.

Finally, the invention also provides for a diagnostic kit comprising

- a nucleic acid fragment of the invention and a means for detecting the binding between the nucleic acid fragment
 and nucleic acid bound thereto, or
- a set of nucleic acid primers which, when used in a molecular amplification procedure together with the nucleic acid fragment of the invention will result in specific amplification of said nucleic acid fragment, and a means for detecting the amplified nucleic acid fragment.

Diagnostic immunological embodiments

Antibodies could be produced and used for screening strains for protein expression, for determining structural location and for examining bactericidal activity of antibodies against these proteins. Means and measures for producing both monoclonal and polyclonal antibodies against OspH are easily applied by the skilled person on the basis of the teachings herein.

30 It is contemplated that several assays for Lyme disease may be developed using any of the OspH proteins or its epitopes, the corresponding DNA encoding the protein, functionally similar proteins and their epitopes, or by detection of the appropriate mRNA. An indirect ELISA assay could be used with the OspH protein or other antigenic proteins. These methods are similar in principle to those previously described (Magnarelli et al. 1989; Craft et al. 1984; Bergström et al. 1991). Reactive epitopes representing portions of the OspH protein sequences could be utilised in an analogous manner.

Another promising assay is the microcapsule agglutination technique (MCAT) (Arimitsu et al., 1991). In this procedure, microscopic polystyrene beads are coated with Bb antigen and incubated with dilutions of patient serum. After overnight incubation at 4°C, the agglutination patterns are determined. Using whole Bb as antigen, the MCAT has been shown to be highly discriminatory between Lyme disease patients and healthy individuals, with little overlap in agglutination titre, although false positive reactions have been obtained with rheumatoid arthritis patients (Anderson et al. 1988) and leptospirosis samples (Barbour, 1988) An assay using OspH protein alone or in combination with other antigens such as the 94 kDA, 30 kDa and 21 kDa antigens should be feasible. Such combination may increase sensitivity of the assay.

In summary, an embodiment of this part of the invention is a diagnostic composition adapted for the determination of Borrelia burgdorferi sensu lato in a sample, the composition comprising the polypeptide of the invention or prepared thereby, the amount of the polypeptide being effective to detectably react with antibodies present in the sample, the antibodies being directed against Borrelia burgdorferi sensu lato, the composition optionally comprising a detectable label, e.g. as described above. Related to this is another embodiment of the invention, i.e. a method of determining the presence of antibodies directed against Borrelia burgdorferi sensu lato in a sample, comprising incubating the sample with the polypeptide of the invention or prepared by the method of the invention, and detecting the presence of bound antibody resulting from the administration or incubation.

25

Finally, this part of the invention also pertains to a diagnostic kit comprising a polypeptide of the invention and a means for detecting the polypeptide with antibody bound thereto.

5 EXAMPLES

10

Bacterial strains and culture conditions. Borrelia strains used in this study were the following: strain B31 of B. burg-dorferi, a tick isolate from North America (ATCC 35210); strain ACAI of B. afzelii, a human skin isolate from Sweden (Åsbrink et al. 1984); strain Ip90 of B. garinii, a tick isolate from the Asian Russia (Kryuchechnikov et al. 1988). Strain B. burgdorferi B313, a mutant of B. burgdorferi B31 lacking OspA, OspB, OspC and OspD (Sadziene et al. 1993).

Also used were three relapsing fever borreliae species,

15 B. hermsii, B. crocidurae, and B. hispanica, as well as

B. anserina, the causative agent of avian borreliosis.

Borreliae were grown in BSK II medium (Barbour 1984) and the cells were harvested in late-log phase by centrifugation at 5,000 rpm for 20 min.

The Escherichia coli strains DH5 α and BL21 were used for transformation with the recombinant plasmids in, respectively, DNA cloning and gene expression experiments. E. coli strains were grown in Luria broth medium (Gibco BRL, Gaithersburg, MD) supplemented, when required, with carbenicillin (Sigma, St. Louis, MO) at 50 μ g/ml.

Monoclonal antibodies 15G6 and 7D4 were obtained from Dr. Alan G. Barbour (Sadziene et al. 1994)

DNA fragments were sequenced by the dideoxy chain termination method, with ABI PRISM™ Dye Terminator Cycle Sequencing Ready 30 Reaction Kit, with AmpliTaq® DNA Polymerase, FS. The sequence

fragments were assembled using the GCG software for UNIX computer.

EXAMPLE 1

Preparation of Bb proteins, sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE), and Western blot

1.1 Preparation of Bb proteins.

For the whole-cell protein preparations, bacteria harvested from 250 ml of BSK II medium were washed twice with phosphate-buffered saline-5mM MgCl_2 , (PBS-Mg). The pellet was suspended in 2 ml of PBS, sonicated and the supernatant was collected after centrifugation at 10,000 rpm for 30 min.

The subcellular fraction of borreliae outer membrane components (designated Fraction B) was prepared as described elsewhere (WO 90/04411). Briefly, cells harvested from 1.5 l of the culture were washed three times with 10 mM Tris-HCl (pH 7.4), 150 mM NaCl and 5 mM MgCl₂. (TSM buffer). Octyl-β-D-glucopyranoside (OGP) (Sigma St. Louis, MO) was added to a final concentration of 2% in 10 ml TSM buffer and the suspension was incubated at 37°C for 60 min. The cell lysate was centrifuged and the supernatant was incubated at 56°C for 30 min. The precipitate was removed by centrifugation at 20,000 rpm for 30 min at 37°C, and the supernatant was dialysed against water at 4°C for 2 days. The precipitate (Fraction B) formed in the dialysis bag was recovered by centrifugation at 20,000 rpm for 30 min at 25°C.

1.2 Separation of proteins by SDS-PAGE.

Bacterial proteins were separated by 15% SDS-PAGE essentially according to Laemmli (1970). Subsequently, gels were either stained with Coomassie Blue R-250 (CB) (Sigma, St Louis, MO), Silver-staining (BioRad Hercules, CA), or were subjected to Western blotting.

1.3 Western blotting.

The proteins were transferred to PVDF-membrane (BioRad, Hercules, CA) by electroblotting at 0.8 mA/cm² for 1 h. The non-specific binding was blocked by immersing the filter for 2 h into 5% non-fat milk powder (Semper, Stockholm, Sweden) in PBS, containing 0.05% Tween-20 (PBS-T). Primary or secondary antibodies were diluted with 2.5% milk-powder in PBS-T, and both incubations of the filter for 1 h was followed by washing in PBS-T. In a developing reaction the substrate for the alkaline phosphatase conjugate was 5-bromo-4-chloro-3-indolyl phosphate (BCIP) (Sigma, St. Louis, MO).

EXAMPLE 2

Preparation of antiserum against the 13 kDa antigen

2.1 Purification of the 13 kDa antigen

15 A 13 kDa protein was purified by 15% SDS-PAGE of Fraction B obtained from the *B. burgdorferi* B313 spirochaetes. The appropriate band was visualised by staining the gel with 250 mM KCl in ice-cold water without fixation in MeOH and Acetic acid. Elution of protein from the gel was performed in a 20 Schleicher and Schuell Biotrap in 15 mM NH₄HCO₃ (200V for 8 hr).

2.2 Immunisation of rabbits.

A mixture of eluted protein and protein from chrushed SDS-PAGE gel of approximately 100 μg of the 13 kDa protein prepared as described above was homogenised and used in each of four immunisations of one rabbit performed in one and two (for the last immunisation) months intervals. Serum samples were obtained during a 5 months period, and serum was diluted 1:1,000 when used for Western blot analysis.

EXAMPLE 3

Cell surface proteolysis of Borrelia cells

3.1 Protease treatment of borreliae cells.

Cell surface proteolysis of Bb cells was conducted as previ-5 ously described (Barbour et al. 1984). Briefly, washed spirochaetes were resuspended in PBS-Mg at a concentration of 2 \mathbf{x} 10^9 cells/ml. To 950 μ l of the cell suspension was added 50 μ l of one of the following: distilled water, proteinase K (Sigma, St Louis, Mo.) (4 mg/ml in water) or trypsin (Gibco BRL, Gaithersburg, MD) (1 mg/ml in 10⁻³ M HCl). After incubation for 40 min at 20°C the proteolytic treatment was stopped by the addition of 10 μ l from a solution of the peptidase inhibitor phenylmethylsulfonyl fluoride (PMSF) (Sigma, St. Louis, MO) (50 mg of PMSF per 1 ml of isopropanol), and the cells were centrifuged and washed twice with PBS-Mg. The 15 pellets were resuspended in TSM buffer. One-third of the cell suspension of each preparation was subjected to the whole cell protein extraction by boiling in SDS-PAGE sample buffer. The remaining part of the suspensions were used to prepare the subcellular fraction of the borrelial outer membrane components, Fraction B, as described above.

3.2 Analysis of the protease treated Borrelia cells.

The result of the protease treatment of Bb cells as analyzed by SDS-PAGE is presented in Figure 1A, and followed by Western Blot, Figure 1B. As seen in the CB stained protein profiles of the whole-cell lysates (Figure 1A), proteinase K affected considerably the minor protein with an apparent molecular weight of 13 kDa. The protein composition of the subcellular fractions of outer membrane components (Fraction B) recovered from protease treated and untreated spirochaetes, was also investigated. The 13 kDa protein was shown to constitute a substantial part of the Fraction B, obtained from the Bb cells. In the Fraction B derived from the proteinase K treated cells, the 13 kDa protein was entirely absent.

The finding that protease treatment eliminate the 13 kDa protein clearly shows that the 13 kDa protein is surface exposed, and most probably associated with the outer membrane of the Bb cells.

5 EXAMPLE 4

Immunogold labelling of Borrelia cells

The monoclonal antibody 15G6 raised against the 13 kDa protein was used as the primary antibody for immunogold staining of intact B. burgdorferi B31, and, B. burgdorferi B313. Cells from strain B31 (Figure 2A) was labelled to a less extent than cells from the strain B313 (Figure 2B). This was probably due to the presence of outer surface proteins, i.e. OspA, OspB, OspC, OspD, on the surface of the B31 cells. The labelling was confined to the outer surface membrane for both strains indicating that the 13 kDa protein is an outer surface protein.

EXAMPLE 5

25

Expression of the 13 kDa protein in different Borrelia species

20 5.1 SDS-PAGE analysis.

The CB stained SDS-PAGE of the whole-cell protein preparations of Lyme disease borreliae is shown in Figure 1A. The 13 kDa protein was present in the whole-cell preparations (WC) and enriched in the membrane fraction (BF) of B. burgdorferi B31, B. afzelii ACAI, and B. garinii Ip90. The PAGE revealed no major differences among the borrelial strains in respect of either apparent molecular weight or expression level of the 13 kDa protein. In the analogous preparations from B. hermsii, B. crocidurae and B. anserina, no visible band corresponding to the 13 kDa protein was detectable.

5.2 Western blotting.

In Western blot analysis of Fraction B prepared from B. burg-dorferi B31, B. afzelii ACAI and B. garinii Ip90(Figure 3A and 3B), the 13 kDa protein of B. burgdorferi B31 reacted with the monoclonal antibody 15G6. The monoclonal antibody failed to recognise the 13 kDa protein from B. afzelii ACAI, and B. garinii Ip90 indicating that the antibody is directed against a variable epitope.

However, polyclonal rabbit antiserum (described in Example 2.2) was able to recognise the 13 kDa protein from all the three Lyme Disease species, i.e. B. burgdorferi B31, B. afzelii ACAI and B. garinii Ip90. (Figure 1B)

In another Western blot analysis the rabbit antiserum raised against the 13 kDa protein prepared from *B. burgdorferi* B313 did not recognise a 13 kDa protein or any proteins of similar molecular weight from *B. hermsii* or *B. crocidurae* (Figure 1C), or *B. anserina* or *B. hispanica* (data not shown).

These data indicate that 13 kDa protein is unique for Lyme disease borreliae. Conversely, it was shown recently that the ospC gene homologues and OspC-related proteins are present in *Borrelia* species not associated with Lyme borreliosis (Marconi et al. 1993).

EXAMPLE 6

Isolation and N-terminal amino acid sequencing of the 13 kDa 25 protein

6.1 Amino acid sequencing.

The 13 kDa protein band was isolated, and cut from a SDS-PAGE gel and eluted in a Biotrap as described above, Example 2.1. N-terminal amino acid sequencing of the purified 13 kDa protein was attempted but no sequence was obtained. It was concluded that the N-terminus of the 13 kDa was blocked.

Therefore, the purified protein was digested with Staphylococcus aereus V8 protease. The protein cleavage resulted in
two fragments of about equal size. As one of the fragments is
blocked only one can be sequenced. After cleavage the fragments were transferred to a PVDF membrane (Biorad, Hercules,
CA) by soaking the membrane in the protein solution over
night. N-terminal amino acid sequence analysis was performed
on a 477A sequenator (Applied Biosystems, Foster City, CA) at
Umeå University.

N-terminal amino acid sequence of the peptide fragment obtained by protease cleavage of the 13 kDa protein, recovered from the Fraction B of B. burgdorferi B313, resulted in the following sequence

TSKQDPIVPFLLNLFLGFGIGSFAQ

(SEQ ID NO: 1.)

15 6.2 Design of oligonucleotide probe.

The sequence of the 25 amino acid fragment was used to design two oligonucleotides, one designated Y5.2 (SEQ ID NO: 2), and one designated Y6.2 (SEQ ID NO: 3). Codons for the amino acid sequence obtained, SEQ ID NO: 1, were selected by reverse translation based on (1) conclusion that codons containing A 20 or T were favoured and (2) knowledge of published DNA sequences for several Bb proteins. A choice favouring A or T containing codons was based on the observation that the G + C content of Bb is only 28-35% (Burman et al. 1990). These oligonucleotides were use in PCR reaction with DNA prepared from B. burgdorferi B31 as template and a 74 bp fragment was obtained. The PCR fragment was cloned into the T-vector (Novagen, Madison, WI) and sequenced, SEQ ID NO: 4. It was verified that the obtained PCR fragment coded for the Nterminal amino acid sequence of the peptide fragment obtained 30 after protease cleavage of the 13 kDa protein, SEQ ID NO: 1. Based on the sequence of the PCR fragment an oligonucleotide designated Y7 (SEQ ID NO: 5) was designed. This oligonucleotide was to be used as a probe.

EXAMPLE 7

Preparation of Bb DNA libraries

7.1 Extraction of DNA.

Spirochaetes harvested from 400 ml of culture of B. burgdorferi B31, B. burgdorferi B313, B. afzelii ACAI, and B. garinii
Ip90 were washed twice with 50 mM Tris-HCl (pH=7.4) and
resuspended in 10 ml of buffer containing 50 mM Tris-HCl
(pH=7.4), 25% sucrose, and 50 mM EDTA. The cells were lysed
by adding SDS to a final concentration of 2%, lysozyme
(Sigma, St. Louis, MO) (1.5 mg/ml), proteinase K (Sigma, St.
Louis, MO) (0.1 mg/ml), and RNAase A (Sigma, St Louis, MO)
(10 µg/ml). The DNA was extracted with buffered phenol and
ethanol precipitated.

7.2 Construction of DNA libraries.

Restriction enzymes were obtained from Boehringer, Mannheim, Germany. 100 ng of borrelial DNA prepared as described above was completely or partially digested using *EcoRI* and *XbaI* restriction endonucleases separately. For the partial digestions, 1 U of restriction endonuclease was incubated with 100 ng of DNA for 10 min. at 37 C. Twenty nanograms of appropriately digested pUC19 (Pharmacia, Uppsala, Sweden) vector was used for ligations.

EXAMPLE 8

Cloning and sequencing of the gene encoding the 13 kDa pro-25 tein

8.1 Screening of DNA library prepared from B. burgdorferi. The recombinant plasmids were transformed into competent E. coli DH5α cells. Initially, B. burgdorferi B31 and B313 EcoRI digested DNA library was screened with the DNA probe Y7 (SEQ ID NO: 5). This screening did not result in any positive clones.

An RsaI restriction site was identified in the sequence of the PCR fragment, SEQ ID NO: 4. This site was used in a further attempt to clone the gene encoding the 13 kDa protein as described below. DNA prepared from B. burgdorferi B31 was cut with RsaI and the fragment ligated into HincII digested pUC18 (Pharmacia, Uppsala, Sweden) plasmid. The oligonucleotide designated Y7 corresponding to the sequence downstream of the RsaI site, SEQ ID NO: 5, was used together with pUC primers forward and reversed (Pharmacia, Uppsala, Sweden) in a PCR reaction to obtain a DNA fragment corresponding to the 10 downstream part of the gene coding for the 13 kDa protein. Another oligonucleotide designated Y7R corresponding to the sequence upstream of the RsaI site, SEQ ID NO: 6, was constructed and used together with the pUC primers forward and reversed in a PCR reaction with EcoRI digested DNA as tem-15 plate to obtain a DNA fragment corresponding to the upstream part of the gene coding for the 13 kDa protein. However, the obtained total sequence coded for protein of calculated molecular weight 7 kDa. This did not correspond to the expected molecular weight of the full length DNA fragment 20 coding for the 13 kDa protein.

Therefore, a new oligonucleotide designated Y9, SEQ ID NO: 7, was designed and used together with the oligonucleotide Y7R, SEQ ID NO: 6, to generate a new PCR fragment. This PCR fragment was used as a probe to screen a library of XbaI digested DNA prepared from B. burgdorferi B31 in an attempt to isolate a full length DNA fragment encoding the 13 kDa protein.

A recombinant plasmid designated (pLY-100) recovered from one positive $E.\ coli\ {\rm DH5}\alpha$ clone was isolated. The DNA insert of this plasmid was sequenced and found to comprise a gene fragment containing 537 bp including an ATG start codon followed by an open reading frame (ORF), SEQ ID NO: 18.

8.2 Sequencing of gene encoding the 13 kDa protein from B. afzelii ACAI and B. garinii Ip90.

The full-length 13 kDa protein gene was retrieved by PCR amplification followed by ligation into a pT7Blue vector (Novagen, Madison, WI). Multiple amplifications was used to ensure that the DNA Taq polymerase did not introduce any errors in the sequence.

The following primer pairs and number of clones was used to obtain the full-length and double stranded sequence of the gene encoding the 13 kDa protein gene in B. afzelii, ACAI and B. garinii Ip90.

	# of B. afzelii ACAI clones ^a	Primer pairs ^b	Primer pairs ^c
_	1	Y9-Y18	SEQ ID NO: 7 - SEQ ID NO: 13
15	1	Y9-CMV3	SEQ ID NO: 7 - SEQ ID NO: 17
	1	Y9-Y10	SEQ ID NO: 7 - SEQ ID NO: 8
	3	Y12-Y10	SEQ ID NO: 10 - SEQ ID NO: 8
	2	Y13-CMV3	SEQ ID NO: 11 - SEQ ID NO: 17
20	# of B. garinii	Primer pairs ^b	Primer pairs ^c
20	Ip90 clones		
_	Ip90 clones ^a	Y9 - CMV2	SEQ ID NO: 7 - SEQ ID NO: 16
_		Y9-CMV2 Y12-Y10	SEQ ID NO: 7 - SEQ ID NO: 16 SEQ ID NO: 10 - SEQ ID NO: 8
_	2	-	
_	2	Y12-Y10	SEQ ID NO: 10 - SEQ ID NO: 8

^{*} Clones obtained by different PCR amplifications.

8.3 Sequence analysis.

30 Sequence analyses were performed using the University of Wisconsin GCG Sequence Analysis Software Version 7.2 for UNIX computer. Search in protein sequence databases was performed at the NCBI using the BLAST network service.

The nucleotide sequence of the gene encoding the 13 kDa protein of B. burgdorferi B31, B. afzelii ACAI, B. garinii Ip90, are shown in SEQ ID NO: 18, SEQ ID NO: 20, and SEQ ID

b Primer pairs used in different PCR amplifications

c Primer pairs used identified by SEQ ID numbers

NO: 22, respectively. The ATG start codon was followed by ORF of 534 and 531 nucleotides for, respectively strains, ACAI and Ip90.

The nucleotide sequence of the gene encoding the 13 kDa protein of *B. burgdorferi* B313 was identical to the nucleotide sequence of the gene encoding the 13 kDa protein of *B. burgdorferi* B31.

The deduced amino acid sequence of the 13 kDa protein of B. burgdorferi B31, B. afzelii ACAI and B. garinii Ip90 is presented in SEQ ID NO: 19, SEQ ID NO: 21 and SEQ ID NO: 23. 10 The deduced amino acid sequence of the full length protein consists of 179, 178 and 177 amino acids for the respective strain. The computer analysis predicted a potential leader peptidase II cleavage site between amino acid residues at position 12 and 13 (LXXF-C), and the N-terminal peak was found on the hydrophobicity plot (data not shown). Based on this and the fact that the protein was found to be N-terminally blocked it was concluded that the 13 kDa protein is a lipoprotein. The 13 kDa protein possesses features, e.g. lipidation and surface exposure, that are characteristic for 20 outer surface proteins (Osp) of Bb and was therefore designated OspH. Surprisingly, the processed OspH protein from the strains B31, ACAI and Ip90 consisted of, respectively, 167, 166 and 165 amino acids with a calculated molecular weight of 18504 Da, 18596 Da and 18620 Da, including a palmitoyl-25 glyceride modification of the cysteine, in contrast to the apparent molecular weight 13 kDa observed on PAGE.

The amino acid sequence of the OspH protein from B. burgdorferi B31 was 87,9 % and 87,5 % identical to the sequences 30 from, respectively, B. afzelii ACAI and B. garinii Ip90. When compared with each other, the two latter strains showed 90,5 % identity.

The level of similarity and identity between the deduced amino acid sequence of the OspH protein from different

borrelia strains further shows that this protein can be useful as a vaccine against Lyme disease as well as a target for diagnostic use.

The OspH proteins were examined for the sequence similarity
to other known proteins in database libraries. There were no
other sequences related significantly to the OspH proteins.
The best hit in an EMBL database search was a 95 residues
long amino acid sequence encoded by the p11 gene on the Bb 49
kb linear plasmid. The encoded amino acid sequence was 41.5%
identical in sequence in a 82 amino acid overlap (corresponding to amino acid residues -12 to 70 in SEQ ID NO: 19). For
the purposes of reference, this best hit is included herein
as SEO ID NOs: 30 and 31.

8.4 Antigenicity plot.

Potential antigenic regions of the deduced amino acid sequences of the OspH proteins from of B. burgdorferi B31, B. afzelii ACAI and B. garinii Ip90 were identified by calculation of the antigenic index using the algorithm of Jameson and Wolf (1988). The results are shown in Figure 4. Proposed epitopic regions having a high antigenic index are e.g. the 20 amino acid sequences corresponding to amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134 and 162-166 in SEQ ID NO: 21, and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23. 25 The numbering of the amino acids is identical to that in the sequence listing, i.e. that the numbering refers to the mature peptide beginning with the 13th amino acid residue in all three sequences, thus excluding the amino acids which are 30 believed to constitute the 12 amino acid leader sequence.

EXAMPLE 9

Localisation of the OspH protein gene

9.1 Separation of DNA by pulse-field agarose gel electrophoresis.

For the pulse-field AGE, the DNA prepared from B. burgdorferi B31, B. burgdorferi B313, B. afzelii ACAI and B. garinii Ip90 was recovered in 1% agarose blocks as previously described (Ferdows and Barbour, 1989). One-dimensional and pulse-field AGE were performed in 1% agarose in TBE buffer. For the pulse-field AGE pulse times were 0.5 s for 30 min. 8 s for 30 min. 1 s for 3 h, 2 s for 3 h, 4 s for 6 h, 8 s for 8 h at a constant current of 200 V. Figure 5A.

9.2 Southern blotting.

Following depurination, denaturation and neutralisation of the gels, the DNA was transferred to Hybond-N membrane (Amersham, Buckinghamshire, UK) by the method of Southern (Sambrook et al. 1989), and cross-linked with UV light. Filters were pre-hybridised and hybridised for, respectively, 1 h and 4 h, and washed. The temperature was 60°C for probing with PCR fragment obtained by amplification using the primers Y7R (SEQ ID:6) and Y9 (SEQ ID:7) (see above) /α-32P/dATP (Amersham, Buckinghamshire, UK, radiolabelled by random primer technique.

The hybridising band corresponded to the position of the 1 25 Mbp linear chromosome of Lyme disease borreliae. Figure 5B.

EXAMPLE 10

Existence of an ospH homologue in related Borrelia species

10.1 DNA.

Total DNA from B. burgdorferi, B. hermsii, B. crocidurae, and 30 B. anserina was digested with EcoRI and separated by AGE.

10.2 Southern blotting.

The filter was probed with a PCR fragment obtained by amplification using primers Y9 (SEQ ID:7) and Y7R (SEQ ID:6).

Hybridisation temperature was 55°C. In general as described in section 9.2.

There was no hybridisation with either the DNA from relapsing fever Borrelia species, B. hermsii, B. crocidurae, nor the avian borreliosis agent B. anserina (Figure 6).

Furthermore, the OspH protein gene being localised to the

chromosome of borreliae shows a higher degree of conservation
among Lyme disease associated borreliae contrary to the
plasmid-encoded major outer surface proteins A, B, and C
which exhibit a significant species and strain dependent
genetic and antigenic polymorphism (Barbour 1986, Jonsson et

al. 1992, Wilske et al. 1993).

EXAMPLE 11

Expression of the OspH protein from B. burgdorferi B31 in E. coli

11.1 Expression of full-length OspH.

Two oligonucleotide primers, Y14 SEQ ID NO: 12 and Y33 SEQ ID NO: 15, were designed to anneal to the 5' end containing the lipidation signal and the 3' end of the OspH gene from B. burgdorferi B31. The primers contained, respectively, BamHI and EcoRI restriction sites, and were used to amplify the OspH gene in the PCR. PCR amplification was performed using Ampli-Taq DNA polymerase (Perkin Elmer Cetus, Norwalk, CT). The PCR product was then treated with the mentioned restriction enzymes, purified by AGE and ligated in fusion with GST (Glutathione S-transferase) into the tac promoter based expression vector pGEX-2T (Pharmacia, Uppsala Sweden). The recombinant plasmid, designated pLY313F, was then used to transform E. coli DH5α cells. E. coli DH5α cells containing

the insert were grown and induced with by adding isopropyl-β-D-thiogalactopyranoside (IPTG) (Sigma, St. Louis, MO) to a final concentration of 1 mM to express the introduced OspH gene. The OspH gene product was subsequently identified by SDS-PAGE (Figure 7A) and Western blot with monoclonal antibody 15G6 against the OspH protein (Figure 7B).

11.2 Expression of truncated OspH.

A similar procedure was used to obtain a truncated variant, i.e. lacking the signal peptide. An oligonucleotide primer,

10 Y13 SEQ ID NO: 11, was designed to anneal to the 5´ end without the lipidation signal sequence) of the OspH gene from B. burgdorferi B31. The primer also contains a BamHI restriction site. The primer was used together with the primer Y33 (SEQ ID NO: 15) in a PCR reaction to amplify the part of the OspH gene without the DNA sequence encoding the signal sequence. A recombinant plasmid designated pLY313T was prepared, E. coli transformed and grown as described above. The truncated OspH gene product was subsequently identified by SDS-PAGE (Figure 7A) and Western blot with monoclonal antibody 15G6 against the OspH protein (Figure 7B).

EXAMPLE 12

30

DNA vaccination

12.1 Preparation of DNA constructs.

To enable expression of *B. burgdorferi* B31 OspH in mammalian cells, the natural leader sequence of the gene ospH was replaced with the human tissue plasminogen activator (hTPA) leader sequence and cloned into the expression vector VR1020 (Luke et al. 1997) to yield plasmid pLY-H (Figure 8A). A similar plasmid enabling the expression of *B. burgdorferi* B31 OspH in translational fusion with OspA was designed pLY-HA (Figure 10B).

More specifically, the DNA encoding TPA 5' UTR and leader peptide, OspH and OspA were isolated from previous plasmid constructs or amplified. In pLY-H the TPA signal was isolated from VR2210 (Luke et al . 1997) by digestion with PstI/KpnI.

The ospH gene was PCR amplified from pLY100 using the primers

The ospH gene was PCR amplified from pLY100 using the primers L1 (SEQ ID NO: 24) and L2 (SEQ ID NO: 25). The ospH containing fragment was digested with KpnI/XbaI and introduced together with the PstI/KpnI isolated TPA signal into VR1020 digested with PstI/XbaI.

10 In pLY-HA the TPA signal was PCR amplified with the primers L5 (SEQ ID NO: 28) and L6 (SEQ ID NO: 29). The OspH gene was PCR amplified from pLY100 using the primers L3 (SEQ ID NO: 26) and L4 (SEQ ID NO: 27) The PCR fragments were digested with the appropriate restriction enzymes. The OspA gene was 15 isolated from VR2210 by digestion with KpnI/XbaI. All three fragments were combined in a three fragment ligation into the PstI/XbaI digested VR1020 to yield pLY-HA.

12.2 Vaccination of mice.

Mice will be injected with the plasmids pLY-h and pLY-HA as well as a negative control plasmid not containing a coding sequence for a *Borrelia* antigen. The plasmid and control DNA are diluted in standard saline. Three bilateral injections of DNA will be given at two week intervals at a dosage of 50 μ g/leg into the *rectus* femoris muscle.

25 12.3 Analysis of immune response.

Sera will be collected after each injection and analyzed by 1) Antibody ELISA and 2) Growth Inhibition of spirochaetes.

12.4 Challenge with Bb spirochaetes.

After the last injection, mice will be challenged with B. burgdorferi sensu stricto N40 spirochaetes (same OspA sero group as B31). Spirochaetes will be either injected intradermally in the tail or by the tick challenge model (Telford et al. 1993). Mice will be sacrificed following the challenge. Bladder, heart, plasma, and cross-cuttings of the tibiotarsal joints will be cultured in growth medium. Cultures will be examined for the presence of spirochaetes by phase-contrast microscopy and scored as negative if no spirochaetes are seen in 50 high-power fields.

5 EXAMPLE 13

Attempted cloning of the ospH gene encoding the 13 kDa protein using monoclonal antibodies.

The clone pMG2 was obtained from Dr. Michael Norgard's laboratory. This clone had been isolated from a library prepared from partial Sau3AI digested DNA of Borrelia burgdorferi 297 cloned into the BamHI site of the plasmid pGEX-1 (Pharmacia). The library had been screened with the monoclonal antibody 15G6. After IPTG induction of E. coli DH5α transfected with the plasmid pMG2 a glutathione-Stransferase (GST) fusion protein reacting with the monoclonal antibody 15G6 could be seen in an immunoblot experiment. The fusion protein had a molecular weight of about 36 kDa, 26 kDa for the fusion partner GST plus 10 kDa for the Bb protein fragment.

20 According to restriction mapping, this clone contained an approximately 300 base pair insert. DNA sequencing showed an open reading frame of 251 bases. The insert was PCR amplified, oligolabelled, and used as a probe to screen libraries prepared from partial *Hind*III digested DNA from *B*.

25 burgdorferi B31, B. afzelii ACAI, and B. garinii Ip90, respectively.

Two positive clones were obtained from each *Borrelia* species and subsequently sequenced. A complete sequence determination were obtained from B31 and Ip90 and a partial sequence was obtained from ACA1 (first half of the gene). The nucleotide sequences where found to encode a 27 kDa protein in size

which did not coincide with the expected size of the 13 kDa protein from Bb.

Furthermore, in another expression experiment we studied the expression in *E. coli* of IPTG induced pMG2 and the above mentioned Bb derived clones using the monoclonal antibody 7D4. After induction *E. coli* transfected with all clones as well as the negative control produced two proteins reacting with the antibody, about 36 kDa and 26 kDa in size. These results indicate that the monoclonal antibody 7D4 did not specifically recognise the 13 kDa Bb protein but cross-reacted with other proteins produced by the *E.coli* cells under these conditions.

Later the identified 27 kDa protein has been verified to be encoded by supercoiled plasmids of Bb (Porcella et al. 1996).

CLAIMS

- 1. An isolated nucleic acid fragment which
- encodes a polypeptide fragment which exhibits a substantial immunological reactivity with a rabbit polyclonal antibody raised against a polypeptide having an apparent molecular weight of 13 kDa as determined by SDS-PAGE followed by visualization, said polypeptide being derived from Borrelia burgdorferi B313 and consisting of the amino acid sequence 1-167 of SEQ ID NO: 19, said rabbit polyclonal antibody exhibiting substantially no immunological reactivity with proteins from at least 95% of spirochaetes randomly selected from the group consisting of Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica, and/or
- hybridises readily under highly stringent hybridization conditions with a DNA fragment having a nucleotide sequence selected from the group consisting of SEQ ID NO: 18, SEQ ID NO: 20, and SEQ ID NO: 22, or with a DNA fragment complementary thereto, but exhibits no substantial hybridization when the hybridization conditions are highly stringent with genomic DNA from at least 95% of spirochaetes randomly selected from the group consisting of Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- 25 2. The nucleic acid fragment according to claim 1, which encodes a polypeptide fragment comprising an amino acid sequence comprised in a polypeptide, said polypeptide being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, and/or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica.

- 3. The nucleic acid fragment according to claim 1 or 2, whichencodes a polypeptide fragment comprising at least a part of an amino acid sequence of a protein having an apparent molecular weight of 13 kDa, said protein being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, and/or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- The nucleic acid fragment according to any of the preceding claims, which encodes a polypeptide fragment comprising at least one epitope, said epitope being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- 5. The nucleic acid fragment according to any of the preceding claims, which encodes a polypeptide fragment comprising at least one epitope of a protein having an apparent molecular weight of 13 kDa, said protein being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- 30 6. The nucleic acid fragment according to any of the preceding claims, which encodes a polypeptide fragment which has an amino acid sequence exhibiting a sequence identity of at least 50% with SEQ ID NO: 19, SEQ ID NO: 21, or SEQ ID NO: 23, or with subsequences thereof having a length of at least 10 amino acid residues.

- 7. The nucleic acid fragment according to any of the preceding claims, wherein the nucleotide sequence has a sequence homology of at least 70% with SEQ ID NO: 18, SEQ ID NO: 20, or SEQ ID NO: 22, or with subsequences thereof having a length of at least 12 nucleotides.
- 8. A nucleic acid fragment according to any of the preceding claims, which comprises a nucleic acid fragment encoding a polypeptide fragment which comprises at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134, and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23.
- 9. The nucleic acid fragment according to any of the preceding claims, which encodes a protein having an apparent molecular weight of 13 kDa which is present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but which is substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- 10. The nucleic acid fragment according to claim 9, wherein the encoded protein is present in fraction B from Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.
 - 11. The nucleic acid fragment according to claim 10, wherein the encoded protein is a surface exposed protein of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.
 - 12. A nucleic acid fragment according to any of the preceding claims which comprises a nucleotide sequence encoding a polypeptide fragment which includes an amino acid sequence

selected from the group consisting of SEQ ID NOs: 19, 21; and 23.

- 13. A nucleic acid fragment according to any of the preceding claims, which comprises a nucleotide sequence selected from the group consisting of SEQ ID NOs: 18, 20, and 22.
 - 14. A nucleic acid fragment according to claim 12 which consists of a nucleotide sequence encoding a polypeptide fragment consisting of an amino acid sequence selected from the group consisting of SEQ ID NOs: 19, 21, and 23.
- 10 15. A nucleic acid fragment according to claim 13, which consists of a nucleotide sequence selected from the group consisting of SEQ ID NOs: 18, 20, and 22.
 - 16. A nucleic acid fragment according to any of claims 1-13, which encodes a fusion polypeptide.
- 15 17. The nucleic acid fragment according to claim 16, which encodes a fusion polypeptide which comprises, as a fusion partner, a polypeptide fragment which enhances the immunogenicity of the fusion polypeptide relative to the immunogenicity of a polypeptide not comprising said second fusion partner or which facilitates the expression of the fusion polypeptide in a host cell and/or the subsequent purification of the polypeptide.
- 18. The nucleic acid fragment according to claim 16 or 17, which encodes a fusion polypeptide comprising as a fusion25 partner a polypeptide fragment which
 - has the same amino acid sequence as at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135, and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134 and 162-166 in SEQ ID NO: 21;

and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133, and 161-165 in seq ID NO: 23,

- is a lipoprotein selected from the outer membrane lipoprotein from E. coli and OspA from Borrelia burgdorferi sensu lato.
- is a viral protein selected from Hepatitis B surface antigen, Hepatitis B core antigen, and the influenza virus non-structural protein NS1,
- is an immunoglobulin binding protein selected from protein A, protein G, and the ZZ-peptide SAME AS ABOVE,
 - is a T-cell epitope,

- is a B-cell epitope,
- is a bacterial fimbrial protein selected from the pilus components pilin and papA, and/or
- is the maltose binding protein, gluthatione S-transferase, β -galactosidase, calmodulin binding protein or poly-histidine.
 - 19. The nucleic acid fragment according to any of the preceding claims, which is a DNA fragment.
- 20 20. A polypeptide fragment which exhibits a substantial immunological reactivity with a polyclonal rabbit antibody raised against a polypeptide having an apparent molecular weight of 13 kDa as determined by SDS PAGE followed by visualization and being derived from Borrelia burgdorferi B313,
- said polypeptide comprising the amino acid sequence 1-167 of SEQ ID NO: 19, said polyclonal rabbit antibody exhibiting substantially no immunological reactivity with whole cell preparations from at least 95% of randomly selected B. hermsii, B. crocidurae, B. anserina, or B. hispanica,

with the proviso that said polypeptide is essentially free from other Borrelia-derived antigens when it is identical in amino acid sequence to a 13 kDa surface exposed polypeptide which can be extracted from Borrelia burgdorferi sensu lato,

5 the polypeptide fragment optionally being lipidated.

- 21. The polypeptide fragment according to claim 20, which comprises an amino acid sequence comprised in a polypeptide, said polypeptide being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, or Borrelia hispanica.
- 22. The polypeptide fragment according claim 20 or 21, which comprises at least a part of the amino acid sequence of a protein having an apparent molecular weight of 13 kDa, said protein being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
- 23. A polypeptide fragment according to any of claims 20-22 comprising at least one epitope, said epitope being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.
 - 24. A polypeptide fragment according to any of claims 20-23, which comprises at least one epitope of a protein having an apparent molecular weight of 13 kDa, said protein being

present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI but being substantially absent from whole cell preparations of at least 95% of randomly selected Borrelia hermsii, Borrelia crocidurae, Borrelia anserina, and Borrelia hispanica.

- 25. The polypeptide fragment according to claim any of claims 20-24, which comprises at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134, and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23.
- 26. The polypeptide fragment according to any of claims 20-15 25, which has an amino acid sequence identical to that of a protein having an apparent molecular weight of 13 kDa and being present in whole cell preparations of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.
- 20 27. The polypeptide fragment according to claim 26, wherein the protein is present in fraction B from Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.
- 28. The polypeptide fragment according to claim 26 or 27, wherein the protein is a surface exposed protein of Borrelia burgdorferi B31, Borrelia burgdorferi B313, Borrelia garinii IP90, or Borrelia afzelii ACAI.
- 29. The polypeptide fragment according to any of claims 20-28, which has an amino acid sequence exhibiting a sequence identity of at least 50% with an amino acid sequence selected from SEQ ID NOs: 19, 21, and 23, or with a subsequence thereof of at least 10 amino acids.

- 30. A polypeptide fragment according to any of claims 20-29, which is encoded by a nucleotide sequence exhibiting a sequence identity of at least 70% with a sequence selected from the group consisting of SEQ ID NOs: 18, 20, and 22, or with a subsequence thereof of at least 12 nucleotides.
 - 31. The polypeptide fragment according to claim 29 which comprises an amino acid sequence selected from SEQ ID NOs: 19, 21, and 23.
- 32. The polypeptide fragment according to claim 31, which is encoded by a DNA fragment comprising a nucleotide sequence selected from SEQ ID NOs: 18, 20, and 22.
 - 33. A fusion polypeptide comprising as a first fusion partner the polypeptide according to any of claims 20-32.
- 34. The fusion polypeptide according to claim 33, which
 15 comprises, as a second fusion partner, a polypeptide fragment which enhances the immunogenicity of the fusion polypeptide relative to the immunogenicity of a polypeptide not comprising said second fusion partner or which facilitates the expression of the fusion polypeptide in a host cell and/or
 20 the subsequent purification of the polypeptide.
 - 35. The fusion polypeptide according to claim 33 or 34, wherein at least one second fusion partner is a polypeptide
- which has the same amino acid sequence as at least one amino acid sequence selected from the group consisting of amino acid residues 7-15, 21-24, 29-35, 83-92, 126-135 and 162-167 in SEQ ID NO: 19; amino acid residues 7-14, 20-23, 28-35, 82-89, 125-134, and 162-166 in SEQ ID NO: 21; and amino acid residues 6-14, 18-21, 27-34, 79-92, 125-133 and 161-165 in seq ID NO: 23,

- which is a lipoprotein selected from the outer membrane lipoprotein from *E. coli* and OspA from *Borrelia burgdorferi sensu lato*,
- which is a viral protein selected from Hepatitis B surface antigen, Hepatitis B core antigen, and the influenza virus non-structural protein NS1,
 - which is an immunoglobulin binding protein selected from protein A, protein G, and the synthetic ZZ-peptide,
 - which is a T-cell epitope,
- 10 which is a B-cell epitope,
 - which is a bacterial fimbrial protein selected from the pilus components pilin and papA, and/or
 - which is the maltose binding protein, gluthatione S-transferase, β -galactosidase, or poly-histidine.
- 15 36. A non-borrelial vector carrying the nucleic acid fragment according to any of claims 1-19.
 - 37. The vector according to claim 36 which is capable of autonomous replication.
- 38. The vector according to claim 36, which is selected from the group consisting of a plasmid, a phage, a cosmid, a minichromosome, and a virus.
 - 39. A vector according to any of claims 36-38 which, when introduced in a host cell, is integrated in the host cell genome.
- 25 40. A vector according to any of claims 36-39, wherein the vector comprises, in the 5'→3' direction and in operable linkage, a promoter for driving expression of the nucleic

acid fragment according to any of claims 1-19, a nucleic acid sequence encoding a leader peptide enabling secretion of or integration into the membrane of the polypeptide fragment, the nucleic acid fragment according to any of claims 1-19, and a nucleic acid sequence encoding a terminator.

- 41. A vector according to claim 40, wherein the promoter drives expression in a eukaryotic cell.
- 42. A vector according to claim 40 or 41, wherein the leader peptide enables secretion from or integration into the mem10 brane of a mammalian cell.
 - 43. A transformed cell carrying the vector of any of claims 36-42 and capable of replicating the nucleic acid fragment according to any of claims 1-19.
- 44. A transformed cell according to claim 43, which is a microorganism selected from a bacterium, a yeast, a protozoan, or a cell derived from a multicellular organism selected from a fungus, an insect cell, a plant cell, and a mammalian cell.
- 45. A transformed cell according to claim 44 which is a 20 bacterium of the genus Escherichia, Bacillus or Salmonella.
 - 46. A transformed cell according to claim 45, which is an *E. coli* cell.
- 47. A stable cell line producing the polypeptide according to any of claims 20-35, which carries the vector according to 25 any of claims 36-42 and which expresses the nucleic acid fragment according to any of claims 1-19.
 - 48. A method of preparing a polypeptide fragment as defined in any of claims 1-19, the method comprising

- culturing the transformed cell according to any of claims 43-46 or the stable cell line according to claim 47 under conditions facilitating the expression of the polypeptide fragment thereby, and
- 5 harvesting the polypeptide fragment, and optionally subjecting the polypeptide to post-translational modification(s);

or

- synthesising the polypeptide fragment by solid-phase
 peptide synthesis or by liquid-phase peptide synthesis.
 - 49. A method according to claim 48, wherein the post-translational modifications involve lipidation, glycosylation, cleavage and/or elongation.
- 50. A vaccine comprising an amount of the polypeptide frag15 ment according to any of claims 20-35 or of the polypeptide
 fragment prepared by the method according to claim 48 or 49,
 the amount of the polypeptide fragment being effective to
 confer substantially increased resistance to infections with
 Borrelia burgdorferi sensu lato in an animal, including a
 20 human being, the polypeptide fragment being formulated in
 combination with a pharmaceutically acceptable carrier,
 diluent or vehicle and the vaccine optionally further comprising an adjuvant.
- 51. A vaccine according to claim 50, wherein the pharmaceuti25 cally acceptable carrier, vehicle, or diluent is selected
 from the group consisting of sterile water, physiological
 saline, glucose, polyalkalene glycols, and triglycerides; and
 wherein the adjuvant is selected from the group consisting of
 aluminium hydroxide or phosphate (alum), synthetic polymers
 30 of sugars (Carbopol), bacterial cells such as *C. parvum* or
 endotoxins or lipopolysaccharide components of gramnegative
 bacteria, physiologically acceptable oil vehicles such as

mannide mono-oleate (Aracel A), a perfluorocarbon (Fluosol-DA).

- 52. A vaccine according to claim 50 or 51, wherein the amount of the polypeptide fragment is in the range 1-1000 μ g per dose unit, such as between 2 and 750 μ g, between 5 and 500 μ g, between 7,5 and 250 μ g, between 10 and 150 μ g, between 10 and 100 μ g, between 10 and 75 μ g, and between 10 and 50 μ g.
- 53. A live vaccine comprising a non-pathogenic microorganism carrying and being capable of expressing the nucleic acid
 10 fragment according to any of claims 1-19 so as to produce the polypeptide fragment according to any of claims 20-35, the live vaccine being effective in conferring increased resistance to infection with Borrelia burgdorferi sensu lato in an animal, including a human being.
- 15 54. The live vaccine according to claim 53, wherein the non-pathogenic microorganism is selected from the group consisting of *Mycobacterium bovis* BCG, Salmonella typhi, Salmonella typhimurium, Salmonella paratyphi, Staphylococcus aureus, and Listeria monocytogenes.
- 20 55. A combination vaccine comprising

an amount of the polypeptide fragment according to any of claims 20-35 or of the polypeptide fragment prepared by the method according to claim 48 or 49, the amount of the polypeptide fragment being effective to confer substantially increased resistance to infections with *Borrelia burgdorferi sensu lato* in an animal, including a human being;

and

25

at least one further Borrelia antigen,

the polypeptide fragment and the antigen being formulated in combination with a pharmaceutically acceptable carrier, vehicle, or diluent and the vaccine optionally further comprising an adjuvant.

- 5 56. A combination vaccine according to claim 55, wherein the at least one further Borrelia antigen is selected from the group consisting of OspA, OspB, OspC, OspD, OspE, OspF, OspG, PC, Oms28, Oms45, Oms 66, decorin binding protein (dbp), LpLA7, EppA, T5, S1, 26 kDa, 39 kDa, 66 kDa, 79 kDa, 85 kDa, and 110 kDa antigen.
- 57. A combination vaccine comprising at least two non-identical polypeptide fragments according to any of claims 20-35 or at least two non-identical polypeptide fragments prepared by the method according to claim 48 or 49, the vaccine comprising an amount of the polypeptide fragments effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being, in combination with a pharmaceutically acceptable carrier, vehicle, or diluent, the vaccine optionally further comprising an adjuvant.
- 58. A vaccine comprising the nucleic acid fragment according to any of claims 1-19 or a vector according to any of claims 36-42, the vaccine effecting in vivo expression of antigens by an animal, including a human being, to whom the vaccine 25 has been administered, the amount of expressed antigens being effective to confer substantially increased resistance to infections with Borrelia burgdorferi sensu lato in an animal, including a human being.
- 59. A diagnostic composition adapted for the determination of Borrelia burgdorferi sensu lato in a sample, the composition comprising the polypeptide fragment according to claim any of claims 20-35 or the polypeptide fragment prepared by the method according to claim 48 or 49, the amount of the polypeptide fragment being effective to detectably react with

antibodies present in the sample, the antibodies being directed against Borrelia burgdorferi sensu lato, the composition optionally comprising a detectable label.

- 60. A diagnostic composition adapted for the determination of Borrelia burgdorferi sensu lato in a sample the composition comprising an amount of the nucleic acid fragment according to any of claims 1-19 which is effective to detectably bind to a nucleic acid fragment from Borrelia burgdorferi sensu lato present in the sample, the composition optionally comprising a detectable label.
- 61. A method of immunizing an animal, including a human being against infections with *Borrelia burgdorferi sensu lato*, the method comprising administering to the animal an immunogenically effective amount of the vaccine according to any of claims 50-58.
 - 62. A method of determining the presence of antibodies directed against Borrelia burgdorferi sensu lato in a sample, comprising incubating the sample with the polypeptide fragment according to any of claims 20-35 or with the polypeptide fragment prepared by the method according to claim 48 or 49, and detecting the presence of bound antibody resulting from the administration or incubation.
 - 63. A method of determining the presence of Borrelia burgdorferi sensu lato nucleic acids in a sample, comprising incubating the sample with the nucleic acid fragment according to
 any of claims 1-19, and detecting the presence of hybridized
 nucleic acids resulting from the incubation.
 - 64. A method for determining the presence of Borrelia burgdorferi sensu lato nucleic acids in a sample, comprising

 subjecting the nucleic acid fragment according to any of
 claims 1-19 to a molecular amplification reaction, such as
 PCR, and detecting the presence of amplified nucleic acid
 which is specific for Borrelia burgdorferi sensu lato.

20

65. A diagnostic kit comprising

- a polypeptide fragment according to any of claims 20-35 and a means for detecting the polypeptide fragment with antibody bound thereto,
- 5 a nucleic acid fragment according to any of claims 1-19 and a means for detecting the binding between the nucleic acid fragment and nucleic acid bound thereto, or
- a set of nucleic acid primers which, when used in a molecular amplification procedure together with the
 nucleic acid fragment according to any of claims 1-19, will result in specific amplification of said nucleic acid fragment, and a means for detecting the amplified nucleic acid fragment.
- 66. A method for the preparation of an immunological composition such as a vaccine, the method comprising the steps of admixing
 - a polypeptide fragment according to any of claims 20-35
 or prepared according to the method of claim 48 or 49,
- a pharmaceutically carrier, vehicle, or diluent, and
 optionally
 - an adjuvant.
